Second, we must recognize that meeting water needs in the Central Valley will be dependent upon controlling and conserving portions of these flood flows for future use. The recently completed DWR publication "Status and Trends of Delta-Suisun Services," May 2007, contains an important illustration of this problem. At page 18 (reproduced here) the authors present a chart entitled "Delta Water Balance" depicting Delta inflows, outflows and exports for three recent water years, 1998 (wet), 2000 (average) and 2001 (dry). Of particular note is the finding that exports from the Delta by the CVP and SWP were less in the wet year which experienced almost 50 million acre-feet of inflow than in the dry year in which less than 14 million acre feet entered the Delta from precipitation and its tributaries. **What kind of a surplus water export system is this?** And how much of the 5,076,000 million acre-feet of exports in the dry year were produced by carry-over storage from project reservoirs as opposed to current year unimpaired flows to which senior water rights and public trust entitlements would generally attach?

Flows vary significantly from year to year

Status and Trends of Delta-Suisun Services
May 2007
HOW TO PREPARE FOR DROUGHT

A simple exercise is illustrative of this point. Average annual exports by the CVP and SWP from the Delta total about 5 million acre-feet, whereas average annual inflows are about 30 million acre-feet. Thus if less than 20% of the annual inflow to the Delta was exported in each year, total exports would increase, while exports during the driest years would be limited to 1 to 2 million acre-feet in each such year allowing sufficient Delta outflow to maintain good water quality in the estuary and support a healthy ecosystem.

It is interesting to note that Dr. Michael Rozengurt, a prominent Russian hydrologist testified in the SWRCB Bay-Delta Estuary Hearing (on July 14, 1987) leading up to D-1379 that every estuary in the world which had significantly reduced its cyclical natural river inflows has experienced serious ecosystem harm. There is a growing scientific consensus that greater outflow, especially in the drier years, will be necessary to support a healthy ecosystem in the estuary, and of the need to determine what the "safe export yield" of the Delta will be after reserving sufficient outflow. Recently, the Pelagic Organism Decline recovery team of scientists has recommended immediate export reductions in the range of 1.5 million acre-feet per year as a measure to avoid elimination of pelagic species.

Should we not be redesigning our massive export projects (and perhaps some others) to increase exports during wetter years while decreasing exports in drier years, all in line with such "safe yield" limits?

The Southern California SWP contractors have already taken steps to accommodate themselves to such an approach with off stream storage and ground water recharge capabilities, as well as with demand management initiatives. But the Central Valley customers have done little. Neither Friant Dam (Millerton Reservoir) nor the Federal share of the San Luis facilities provide much carry-over storage relative to the annual demands of the CVP contractors. Both are largely operated on an annual fill and empty strategy. More wet year storage is needed, but where is it to be found?

Some of it might be provided by new or expanded reservoirs in the mountains, but this is unlikely given the current economics (especially without...
urban subsidies of agricultural supplies), environmental problems, and the impacts of global warming on yield of traditional storage reservoirs.

More than likely it would best be provided by flood plain management on the valley floor, more like it was 150 years ago.

It should be noted that quite a bit of this is already happening. Flood management for the Sacramento Valley is largely provided not by foothill reservoirs, but by a system of bypasses and floodways on the valley floor. Although not much emphasis is placed on flood flow retention and ground water recharge in these by-passes and floodways today, it could be in the future.

The Tulare Lake Basin presents a model for the areas south of the Delta. Much of the larger flows of the Kings River are planned to flow into the basin where they are confined to leved areas and used for carried-over irrigation supplies. These operations could be expanded to include flood waters that are now pushed to the San Joaquin River.

Similarly, the Kern County Water Bank is operated to store excess waters in wet years in a previously over-drafted ground water basin for subsequent use.

Investigation will reveal many other opportunities to retain storm waters on the valley floor in historical flood plains for carry-over use and ground water recharge. Some of these may utilize temporary retention in the by-passes and basins of the Sacramento Valley for subsequent transfer to storage and recharge on the floor of the San Joaquin Valley and Tulare Lake, finally utilizing wetter year export capacity of the CVP and SWP when fewer environmental consequences can be anticipated. Other opportunities will be found around Los Banos in the depleted basins under the San Joaquin River accessed from areas like Madera Ranch, the San Luis Refuge, the Grasslands and from the restoration of flows in the San Joaquin River itself. An intriguing opportunity will be presented as the Department of the Interior pays to retire vast acres (200,000 or more) of the Westlands Irrigation District impaired by perched ground water without drainage but overlying an over-drafted ground water basin beneath the Corcoran Clay.

Reoperation of existing reservoirs will be more feasible with operable flood control basins.

Other opportunities will be presented by the need to create a system of
weirs and gates to supply flood by-passes and retention basins as the weather changes south of the Delta from snow to rain. These may extend all the way into the Delta, with flood easements acquired on currently farmed acreages for temporary flooding or wetlands creation on lands that don’t include critical infrastructure, i.e., controlled flooding and timely pump-out to avoid levee failure and impacts to adjacent lands, to provide better flood protection to urban areas and critical infrastructure.

Easement programs should be developed, perhaps through the creation of a Conservancy, to target critical habitat areas, both aquatic and terrestrial, not already in public ownership, and to help compensate for loss of farming and development opportunities.

It is important to point out that the additional dry-year water that can be supplied by this type of redesign of the CVP and SWP does not need to be exported from the Delta in dry years since it is already at or near the sites where it is needed, recharging depleted ground water basins, recreating historical wetlands and providing carry-over water supplies.

Another important feature is that those projects are primarily designed for flood control, traditionally a non-reimbursable feature of water project development. The resulting water supply may therefore be one that agricultural users could actually afford.

WHAT NEEDS TO BE DONE IN THE DELTA ITSELF?

The Delta is much more than a cross-roads for water development or a vast and fertile farming area. Probably because its land is relatively flat, relatively unpopulated and relatively inexpensive, much important infrastructure has been sited in and across the Delta, all of which is vulnerable to catastrophic levee failures. Increasingly urban development is encroaching into the Delta as well. It is also home to one of the great and most varied ecosystems in the world, both aquatic and terrestrial, as well as a multi-faceted recreational paradise easily accessible to a large and growing population. All of these assets – farming, infrastructure, urban areas, environment, recreation – are as vulnerable to catastrophic levee failure as are the water export facilities, although the exports
facilities draw the most political attention.

In simple terms, agriculture built and maintains the levees, now with modest support from the State through the Levees Subvention Program. The levees protect the homes, highways, aqueducts, pipelines, gas fields, deep water channels, recreation facilities and ecosystem found in the Delta. Water development squeezes as much water as it can out of the Delta during the drier years putting enormous and destructive pressure on the ecosystem and the local uses. In the wetter years, upstream development dumps as much flood water as it can into the tributaries putting enormous pressure on the Delta levees. Is it any wonder that commentators now consider the Delta, if current trends continue ("business as usual"), to be "unsustainable" in the face of future changes?

The "drivers of future change" identified in the Delta Risk Management Study are:

- Subsidence
- Global climate change - sea level rise
- Regional climate change - more winter floods
- Seismic activity
- Introduced species
- Population growth and urbanization

How do we deal with these "drivers"?

**SUBSIDENCE**

Subsidence has occurred both with levees and the lands protected by the levees. As river flood stages have increased due to upstream activities causing constrictions on the flood plain and due to global warming, levees have been increased in width and height. Where constructed on compressible soil foundations (peats and clays), the additional weight has compressed these foundations, causing settlement and necessitating further construction, more weight, and more settlement. Each time new levee height or width is required, the process repeats itself until the foundation soils are fully compressed and
stabilized. Stabilization has largely occurred in many parts of the Delta, especially toward the edges.

The second form of subsidence has occurred mainly through oxidation of organic soils which were dried out (and sometimes burnt for weed control) for farming, and to some degree, by compression of the dewatered soils from the weight of farm equipment, not unlike the first form of subsidence discussed above for the levees. This form of subsidence slows down, and eventually stops, as the organic soils are depleted which has also occurred in most of the Delta. It is estimated by local interests well familiar with current soil conditions, that less than 100,000 of the 600,000 acres in the Delta still contain enough organic material to further subside. Most of these conditions existing in the west-central portions of the Delta, and these soils usually occupy just portions of islands, not the entire island.

Subsidence of the farmed lands has no impact upon levee stability per se. The levee structures support themselves and the “design levee” is only dependent upon a swath of land 200-400 feet wide, which is the foundation upon which the levee is built.

Although farmed land subsidence can increase the volume of water which the leveed island will contain if flooded, it doesn’t contribute significantly to the stability of the levee itself.

Generally speaking, normal levee maintenance has kept up with the problems created by subsidence. The bigger challenges are presented by the next subjects.

GLOBAL CLIMATE CHANGE - SEA LEVEL RISE

Modest sea level rise has been documented at the Golden Gate since the original reclamation of the Delta, about 6 inches since reliable measurements began. Most observers feel this phenomenon is increasing and will produce further rises in a broad range of one to eight feet over the next 50-200 years. At the upper end of this range the world will be dealing with more difficult issues than the Delta, and many coastal areas and bays don’t currently have levee protection.
Because the Delta is already protected by levees (which have few encroachments), it is possible to build higher, wider, stronger levees. It also becomes more expensive as levee building material gets scarcer and more remote. It is critical to protect and expand local sources of scarce material, such as dredged materials from deep water channel maintenance activities and the rock revetment material from nearby quarried deposits, which are under constant regulatory pressure.

At some point “Dutch” solutions should be considered, especially if the rate of sea level rise trends toward the higher estimates. Such solutions include joining groups of islands together behind common levees ("polders") to reduce the miles of levees which need major improvement. In many cases locks would be appropriate to retain waterway access for recreational and commercial uses.

Consideration should likewise be given to the possibility of constructing closable surge barriers west of the Delta if it looks like sea level rise will trend toward the highest estimates, mimicking the Rotterdam Storm Surge barrier types which Dutch engineers are now studying for the Lower and Upper Mississippi River. It would be helpful to have the assistance of the Dutch engineers to help plan an effective future flood control plan.

REGIONAL CLIMATE CHANGE - MORE WINTER FLOODS

Our responses to this “driver of future change” have been described earlier. Suffice it to repeat here that we need a Central Valley Flood Management Plan that will identify opportunities to attenuate flood peaks and incorporate methodologies for future use of the attenuated flows through flood plain retention and ground water recharge.

SEISMIC ACTIVITY

This is the real “wild card” of the drivers of future change. Although the Delta has never experienced levee failure from an earthquake, it could tomorrow. Hence, we should be preparing today.

The seismic vulnerability of the Delta is focused overwhelmingly in the
westernmost Delta because of closest proximity to known active faults, poorest levee foundations vulnerable to seismic events, and exposure of the CVP, SWP, and CCWD to potential sea water intrusion at their intake facilities induced by a western Delta island failure. As much as 60-70% of the risk of seismic failure is concentrated on Sherman Island alone, according to the risk studies, and much of the remaining risk is to Jersey, Twitchell and Bradford Islands.

In spite of the fact that most of the lands on these westernmost Delta Islands are already in public ownership, little is being done to reduce seismic vulnerability beyond "hand-wringing." Subsidence is presumably continuing under the farming practices of the tenant farmers and major seismic reinforcement of the most vulnerable portions of the levees is not being accomplished. We believe the public ownership needs to react quickly to the perceived seismic threat. Since these westernmost islands are also the closest and most accessible to the Bay Area population, there is a significant opportunity to meet recreational and educational needs if portions of these lands need to be converted from agriculture to attain seismic protection.

Our engineers tell us that a good defense against seismic failure is to widen the levee so that slumping caused by foundation liquefaction does not take the whole levee section resulting in a breach. In the process, a lot of material has been "stockpiled" at the site which can be used to respond to slumping damage as it occurs.

It should be noted that as you move eastward into the Delta, the seismic risk decreases, as does the risk of induced salinity intrusion which affects intake facilities of the in-Delta diversions. If the westernmost islands don't fail, the exposure of the export facilities is greatly reduced. By way of example, the recent June failure of the Jones Tracts' levees did not significantly impact export water quality. In the Eastern Delta, storm flood is a more significant risk, although as protection for urbanized areas is designed, seismic protection should be incorporated at appropriate levels.
INTRODUCED SPECIES

Introduced species have been identified as a big concern only in the last twenty-five years or so. In fact, some of the species we are now concerned about saving (Striped Bass, Threadfin Shad) are themselves introduced.

The Asian-variety clams and crabs that have become problems weren’t “invented” in the last 25 years, and ocean-going commerce (and bilge water dumping) has existed since at least the 1930’s. Why are they pervasive now, competing for food with the “desired” organisms?

The answer most likely lies in the changes to the aquatic environment which have taken place as a result of upstream diversion and Delta exports of fresh water which would otherwise run through the Delta to Suisun, San Pablo and San Francisco Bays.

The effect has been dampening of seasonal flow and quality fluctuation and, contrary to the mistaken assertions upon which the PPIC Report authors based their conclusions, a saltier Suisun Bay and Delta. The “null” or “mixing” zone where the forces of the Delta fresh water outflows and the ocean tides achieve balance in the spring and summer used to be found in Suisun Bay, which is very wide, typically shallow, and (before the construction of the Montezuma Slough gate), used to have many dendritic excursions into sloughs extending into the Suisun Marsh. Because the null zone is the most nutritionally productive area of the estuary, the combination of primary food production and channel configuration provided a productive nursery area for the aquatic creatures of the system.

Now the mixing zone has been relocated by reduction of Delta outflow an average of seven miles further upstream into the deep, dark, steeply banked channels of the western Delta, conditions in which the “preferred” species do not thrive. The more salt-loving Asiatic clams have taken hold in Suisun Bay and “filter” the zooplankton and other primary food supplies out of the system.

The best, and perhaps only, solution to this problem is to return the null or mixing zone to Suisun Bay by reducing exports from the system during the drier years, which is proposed earlier in this paper. If the water supply offshore from
Suisun Marsh was re-established at quality necessary to grow preferred plants in the Marsh, the dendric sloughs could be re-opened into the Suisun Bay which would undoubtedly help support the "nursery function" of Suisun Bay.

**POPULATION GROWTH AND URBANIZATION**

The population is probably going to continue to grow and that may not be avoidable, or necessarily bad. The key is to keep it from growing into flood-threatened areas.

We have a big problem. Locally governed land use authority allows urban development to occur in areas that turn out to lack adequate flood protection for existing or newly urbanized areas. The federal government doesn’t adequately respond to flood threats, and to floods. As a group, the local, state and federal authorities don’t have a flood management plan.

This problem transcends the entire Central Valley, although it is most evident in the Delta. We need to develop a plan whereby we have a common flood management plan that the local, state and federal authorities can work together to implement and stop pushing the blame (and liability) back and forth amongst each other.

Earlier in this paper we called for the development of a Flood Management Plan for the Central Valley which will assess current and future conditions. With such a plan we can determine how to operate flood control features of water storage projects, where to build our levees, and which portions of the historical flood plain we need to reactivate or recreate “to provide room for the rivers.” Then we will know where, and where not, to build our cities. And there will be a sound basis for dividing governance responsibility between local, regional and state agencies on the basis of designated uses.

**CONVEYANCE**

Once all these "drivers" have been addressed as discussed above, we can "tinker" with Delta conveyance strategies to optimize the system without mere reallocation of shortage.
From a Delta perspective, we are fearful that mechanisms that make it possible to short the Delta of its water supply will be used, ultimately, to short the Delta of its water supply. We also believe that little has been done to consider the implications of isolated transfer since the 1982 Referendum and dispute the recent statement attributed to the Governor that isolated Delta conveyance "has been studied to death." We have the following concerns about isolated transfer facilities:

- The fresh water inflow to the Delta has already been greatly reduced by bypassing the Delta exports south from Friant, west from the Tuolumne, and west from the Mokelumne. The Inflow is also reduced by the consumptive use of upstream water to grow food and support urban growth. If a Peripheral Canal were used to also keep Sacramento water out of the Delta, there would inevitably be further substantial increase in the salinity of water in Delta channels. Exports from Delta channels would then be deemed too salty. The canal would, therefore, have to convey all the water that is now exported south and west from Delta channels.

- The Peripheral Canal would be a barrier to flood waters from south and east of the Peripheral Canal alignment. During major floods that exceed the capacity of the San Joaquin and Mokelumne channels, the flood stage would increase against levees that protect tens of thousands of homes. The canal itself becomes a potential threat to flood adjacent areas if it breaches (and we are advised that current design and cost estimates do not include seismic protection).

- The Peripheral Canal would require vast expenditures to construct massive new levees on both sides of a 42 mile alignment through the very areas where we now have problems maintaining levees.

- If billions of dollars are spent on a Peripheral Canal, those funds won't be available to improve existing Delta levees, and to implement measures that could impede the flow of Bay water into the Delta in the event of multiple levee break if it occurs at a time when outflow to the Bay is not maintained by flood flows.

- If the basic configuration of Delta channels and land uses is not maintained, there will be an increase in the tidal encroachments which brings Bay water
into the Delta exacerbating water surface elevation during flood flows and loss of water to meet net Delta outflow requirements. Numerous Peripheral Canal proponents propose that levees be breached and/or allowed to fail for lack of maintenance or repair. As each island flooded it would increase Bay water encroachment. “Water use” by evaporation from the surface of flooded lands exceeds agricultural use of water from farmed lands by about two acre-feet per acre. It would also increase wave erosion on other levees. If the basic configuration is not maintained, the Delta will become a salty inland bay.

- As the Delta became an inland bay, the levees that protect roads, housing, utilities, railroads, recreation facilities, etc., would experience substantial wave and seepage problems. Their ability to protect the public’s interests would be seriously diminished. It may be far cheaper to fortify the existing levees that protect the infrastructure than to relocate or fortify the infrastructure itself.

- Delta agriculture now produces food on about half a million acres of Delta lands. The production would be largely destroyed by increased salinity and by the uncertainty of levee protection caused by a Peripheral Canal. Agricultural Code 411 states that California must not become dependent on a net import of food due to failure to provide an adequate agricultural water supply. Using a Peripheral Canal to increase salinity and destroy half a million acres of food production in the Delta is incompatible with that mandate.

- The salinity increase caused by a Peripheral Canal would cause a violation of most, if not all, of the SWRCB’s salinity standards and contracts with Delta water agencies.

- The reallocation of an inadequate water supply and other consequences of a Peripheral Canal would violate the Delta Protection Statutes, water rights law, and the Environmental Protection Act.

- The initial effect of the Peripheral Canal on Delta fishery is controversial. The entire Sacramento River anadromous fishery (Salmon, Steelhead, Shad, Sturgeon, Striped Bass, etc.) would need to pass by its intake and no fish screen of this magnitude has ever been proven effective. Delta Smelt will follow the fresh water in the Delta to the pump intakes (whether they are at Tracy or Hood) when water quality deteriorates below the point of export.
• It is not clear that there is a routing available for a Peripheral Canal with all of the urbanization that has occurred since 1982, without relocating it westward into the very areas that are thought to be vulnerable to flooding because of subsidence, poor foundation material and seepage problems.

• Who would be willing to pay for it? The 1982 Referendum illustrated the reluctance of the voters and a recent court decision reconfirms the obligation of the State to submit bond proposals to the voters.

The proposals to improve the efficiency of passage of water through the interior of the Delta bear more promise from both a political perspective and a "reversibility" perspective, including the recent suggestions of ways to separate the streams carrying fish from the flows being exported in the South Delta while still maintaining sufficient flow through the Delta to maintain a common pool of fresh water for use within and without the Delta.

Recent proposals incorporating such separations include “Straw Proposal 2” the so-called “Eco-Crescent” presented to the Delta Vision Stakeholder Coordination Group at its recent workshop in Courtland on June 13 and 14, and Dr. Russ T. Brown’s “Proposal to Reconnect the San Joaquin River to the Estuary” dated March 23, 2007. Many features of these concepts included within the “Flexible Delta” Scenario being developed by the Delta Visions Stakeholder Coordination Group may fit within this concept, although others would not. In fact, a group composed of representatives of the North, Central and South Delta Water Agencies and some environmental groups submitted a tributary corridors concept to CALFED several years ago which included a physical barrier to separate San Joaquin River Salmon at the head of Old River to keep the fish in the main stem of the San Joaquin River away from the influence of the export pumping from Old River while enhancing other environmental features of Old and Middle Rivers.

All of these proposals appear to provide protection to important Delta fisheries without negatively impacting Delta water quality, such as is the case with isolated (peripheral) transfer facilities, and are worthy of study and consideration in conjunction with the other suggestions made here.
BLUE RIBBON TASK FORCE ISSUE ASSESSMENT

Before concluding, we wish to point out how the approach recommended in this paper responds directly or by implication to the issues which the Governor has addressed to the Blue Ribbon Task Force in his Executive Order 5-17-06 initiating the Delta Vision Process:

- **The environment, including aquatic and terrestrial functions and biodiversity.**

  Our approach is to restore enough of the historical Delta outflow pattern necessary to return the mixing zone to the Suisun Bay to reclaim the ecological vitality of the Bay-Delta Ecosystem, while replacing displaced exports with flood plain recapture, ground water replenishment, and demand management initiatives. This approach will benefit aquatic and terrestrial populations in the entire Central Valley through enhanced drier year stream flow, water quality and wetland restoration, while providing protection to the largest fresh water estuary in the Americas and the 700+ native species of fish, animals and plants that depend upon it.

- **Land use and land use patterns, including agriculture, urbanization, and housing.**

  Developing and implementing a Flood Management Plan for the Central Valley will help resolve existing governance problems by designating, from a regional perspective, where urbanization can safely occur and where agriculture and other open-space uses must remain, and by providing financing to implement the plan. Such a Flood Management Plan would also help determine whether it is more cost effective to protect legacy communities, roads, and other Delta infrastructure by strengthening existing levees or by constructing ring levees or consolidating and armoring utility corridors.

- **Transportation, including streets, roads, highways, waterways, and ship channels.**

  This paper favors maintaining the existing land patterns in the Delta to appropriate risk levels given the protected use. Seismic concerns would be stressed in the westernmost Delta and for levees that protect urban areas. Flood
risks would be addressed through a combination of flood attenuation in upstream flood plains and rehabilitation and maintenance of Delta levees, in accordance with sound engineering practices. Greater risk would be assigned to levees which don’t protect important infrastructure, recognizing the need for both a flood easement program and robust emergency response.

Delta Engineers assure us that there are techniques to protect Delta levees to address seismic risk and future conditions relating to global warming. If global warming begins to reflect higher estimates, "Dutch solutions," such as polders and tidal surge barriers, should be considered for timely implementation.

- Utilities, including aqueducts, pipelines and gas/electric transmission corridors.

As noted above, levee systems that protect at-risk infrastructures should be maintained to less at-risk standards. The utilities themselves are currently involved in this type of planning and construction, including multiple routing and consolidation.

- Water supply and quality, municipal/industrial discharges and urban and agricultural runoff.

The current system of regulation is adequate to meet existing and emerging public health and safety objectives, and to incorporate new technologies as they appear. Public funding needs to be available to address unusual issues, emergencies and environmental justice concerns.

- Recreation and tourism, including boating, fishing and hunting.

This paper's approach would enhance aquatic and terrestrial resources throughout the Central Valley and specifically preserve and support recreation and tourism through appropriate land-use designations established by a Central Valley Flood Management Plan, and by the restoration of a robust fresh water environment in the Delta consistent with its history.

- Flood risk management, including levee maintenance.

This paper calls for establishment and maintenance of levees throughout the Delta appropriate for the protection of the assets they protect and the stresses they will face, and a robust Emergency Response Plan for when, and if, they fail. Ultimately, it is either extremely expensive or impossible, to only protect
some of the levees in the Delta.

- **Emergency response.**

  No matter how well designed and constructed, any levee can fail, if not from earthquake, floods or beavers, then maybe from acts of terrorism. We must have a robust Emergency Response Plan, including quick financial response capability. Delta interests have promoted and participated in emergency response planning, including a set-aside of Propositions I-E and P4 funding to jump start emergency response.

- **Local and state economies.**

  Too often discussion about Delta Vision focuses on water export interruption and ignores the devastating impact a major flooding in the Delta would have on the ecosystem, transportation, utilities and urbanized populations. Any viable Delta Vision cannot envision long-term loss of any significant portion of the Delta land mass or the levees that provide its protection. This paper also describes a methodology for providing the water supply to the Delta exporters which they were supposed to get from the expansion of the water project in a way that addresses flood issues meaningfully with the prospect of global warming and is sensitive to environmental issues.

**CONCLUSION**

We have become dependent, perhaps unwittingly, upon the Delta to support a wide variety of functions, from ecosystem, to agriculture, to transportation of people, water, energy, and commodities, to urban communities and their recreation needs. We need to develop a plan that deals with all of these functions, not just inter-regional water transfer. We need to look beyond the Delta for solutions.

This plan needs to look forward and anticipate changes that appear certain to occur in the twenty-first century and beyond, and not be tied to concepts developed to deal with the past.

We hope that you have found this paper to be useful in that regard.
