The acres of protection contained in the near-term Plan goals satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1 and other near-term impacts. However, the restored riparian habitat would require several years (early-mid successional) and several decades (mature riparian forest), for ecological succession to occur and for restored riparian habitat to functionally replace habitat that has been affected. Because the western yellow-billed cuckoo is not known to be an established breeder in the Plan Area, the time lag in riparian restoration from BDCP actions would not be expected to have an adverse population-level effect on the species. Overall, BDCP riparian habitat restoration actions would be expected to benefit western yellow-billed cuckoo by increasing opportunities for a breeding population to become reestablished in the study area.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, AMM7 Barge Operations Plan, and AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell’s Vireo, Western Yellow-Billed Cuckoo. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.

**Late Long-Term Timeframe**

The habitat model indicates that the study area supports approximately 12,395 acres of modeled breeding and migratory habitat for yellow-billed cuckoo. Alternative 1B as a whole would result in the permanent loss of and temporary effects on 673 acres of modeled habitat (5% of the modeled habitat in the Plan Area). These losses would occur from the construction of the water conveyance facilities (CM1) and from CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, and CM5 Seasonally Inundated Floodplain Restoration. The locations of these losses would be in fragmented riparian habitat throughout the study area.

The Plan includes conservation commitments through CM7 Riparian Natural Community Restoration and CM3 Natural Communities Protection and Restoration to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill riparian woodland. Of the 5,000 acres of restored riparian natural communities, a minimum of 3,000 acres of valley/foothill riparian would be restored within the seasonally inundated floodplain, and 1,000 acres would be managed as dense early to mid-successional riparian forest (Objectives VFRNC1.1 and VFRNC1.2). In addition, at least 500 acres of mature riparian forest would be maintained in CZ 4 or CZ 7 (Objective VFRNC2.3). This mature, riparian forest would be mixed with a portion of the early- to mid-successional riparian vegetation in large blocks with a minimum patch size of 50 acres and a minimum width of 330 feet (Objective VFRNC2.2 and VFRNC2.4), which would provide suitable nesting habitat for the cuckoo.
The protection of 750 acres of existing valley/foothill riparian forest in CZ 7 would not provide in its entirety the vegetative structure needed to support these species, because patch sizes may not be large enough to support yellow-billed cuckoo breeding habitat. However, a portion of the protected habitat would provide suitable habitat for the species. Restoration actions through CM7 and CM11 would expand the patches of existing riparian forest in order to support the species should they become established breeders in the study area.

The BDCP’s beneficial effects analysis (BDCP Chapter 5, Section 5.6, Effects on Covered Wildlife and Plant Species) estimates that the restoration and protection actions discussed above could result in the restoration of 3,397 acres and the protection of 517 acres of habitat for the yellow-billed cuckoo.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, AMM7 Barge Operations Plan, and AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell’s Vireo, Western Yellow-Billed Cuckoo. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.

Considering Alternative 1B’s protection and restoration provisions, which would provide acreages of new or enhanced habitat in amounts greater than necessary to compensate for the time lag of restoring habitats lost to construction and restoration activities, and with implementation of AMM1–AMM7 and AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell’s Vireo, Western Yellow-Billed Cuckoo, the loss of habitat or direct mortality through implementation of Alternative 1B would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on western yellow-billed cuckoo.

**Impact BIO-96: Fragmentation of Western Yellow-Billed Cuckoo Habitat as a Result of Constructing the Water Conveyance Facilities**

Grading, filling, contouring, and other initial ground-disturbing operations for water conveyance facilities construction may temporarily fragment modeled western yellow-billed cuckoo habitat. This could temporarily reduce the extent and functions supported by the affected habitat. Because western yellow-billed cuckoo is not currently present in the study area, and because the implementation of CM5 Seasonally Inundated Floodplain Restoration would protect and create contiguous high-value riparian habitat, any such habitat fragmentation is expected to have no or minimal effect on the species.

**NEPA Effects:** Fragmentation of habitat would not have an adverse effect on western yellow-billed cuckoo. The habitat functions in the study area for the species would be greatly improved through the implementation of CM5, which would restore and protect large contiguous patches of riparian habitat.

**CEQA Conclusion:** Fragmentation of habitat would have a less-than-significant impact on western yellow-billed cuckoo. The habitat functions in the study area for the species would be greatly
improved through the implementation of CM5, which would restore and protect large contiguous patches of riparian habitat.

**Impact BIO-97: Effects on Western Yellow-Billed Cuckoo Associated with Electrical Transmission Facilities**

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of western yellow-billed cuckoo. Because the western yellow-billed cuckoo uses riparian forests to meet all of its breeding and wintering life requisites, the species remains primarily within the canopy of riparian forests and rarely ventures into open spaces except during migration, limiting its opportunity to encounter the proposed transmission lines. As a summer resident, the species occurs in the study area during periods of relatively high visibility and clear weather conditions, thus further reducing collision risk from daily use patterns or seasonal migration flights. Finally, western yellow-billed cuckoo wing shape is characterized by low wing loading and a moderate aspect ratio, making the species moderately maneuverable and presumably able to avoid collisions, especially during high-visibility conditions (BDCP Appendix 5.J, Attachment 5J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). Transmission line poles and towers also provide perching substrate for raptors, which could result in increased predation pressure on western yellow-billed cuckoo if they were to use habitat adjacent to lines.

**NEPA Effects:** The risk of bird-strike is considered to be minimal based on the species’ rarity in the study area, its proclivity to remain in the riparian canopy, its presence in the study area during periods of relative high visibility, and its overall ability to successfully negotiate around overhead wires that it may encounter. Transmission line poles and towers also provide perching substrate for raptors, which could result in increased predation pressure on western yellow-billed cuckoo. This would not be expected to have an adverse effect on the western yellow-billed cuckoo population.

**CEQA Conclusion:** The construction and presence of new transmission lines would have a less-than-significant impact on western yellow-billed cuckoo because the risk of bird-strike is considered to be minimal based on the species’ rarity in the study area, its proclivity to remain in the riparian canopy, its presence during periods of relative high visibility, and its overall ability to successfully negotiate around overhead wires that it may encounter. Transmission line poles and towers also provide perching substrate for raptors, which could result in increased predation pressure on western yellow-billed cuckoo. This would be expected to have a less-than-significant impact on the western yellow-billed cuckoo population.

**Impact BIO-98: Indirect Effects of Plan Implementation on Western Yellow-Billed Cuckoo**

Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect western yellow-billed cuckoo use of modeled habitat adjacent to proposed construction areas. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect western yellow-billed cuckoo. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 1,300 feet from the construction edge. If western yellow-billed cuckoo were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging.
and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. These potential effects would be minimized with incorporation of AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell’s Vireo, Western Yellow-Billed Cuckoo into the BDCP. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect western yellow-billed cuckoo in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to western yellow-billed cuckoo habitat could also affect the species. AMM1–AMM7, including AMM2 Construction BMPs and Monitoring, in addition to AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell’s Vireo, Western Yellow-Billed Cuckoo, would minimize the likelihood of such spills and ensure that measures were in place to prevent runoff from the construction area and any adverse effects of dust on active nests.

**NEPA Effects:** Indirect effects on western yellow-billed cuckoo as a result of Plan implementation could have adverse effects on the species through the modification of habitat and potential for direct mortality. However, due to the species’ minimal presence in the study area, and with the incorporation of AMM1–AMM7 and AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell’s Vireo, Western Yellow-Billed Cuckoo into the BDCP, indirect effects would not have an adverse effect on western yellow-billed cuckoo.

**CEQA Conclusion:** Indirect effects on western yellow-billed cuckoo as a result of Alternative 1B implementation could have a significant impact on the species from modification of habitat. With the incorporation of AMM1–AMM7 and AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell’s Vireo, Western Yellow-Billed Cuckoo into the BDCP, indirect effects as a result of Alternative 1B implementation would have a less-than-significant impact on western yellow-billed cuckoo.

**Impact BIO-99: Periodic Effects of Inundation of Western Yellow-Billed Cuckoo Habitat as a Result of Implementation of Conservation Components**

Flooding of the Yolo Bypass from Fremont Weir operations (CM2) would increase the frequency and duration of inundation of approximately 11-20 acres of modeled western yellow-billed cuckoo breeding habitat and 37–64 acres of modeled migratory habitat. No adverse effects of increased inundation frequency on western yellow-billed cuckoo or its habitat are expected because the cuckoo breeding period is outside the period the weir would be operated. In addition, riparian vegetation supporting habitat has persisted under the existing Yolo Bypass flooding regime, and changes to frequency and inundation would be within the tolerance of these vegetation types.

Based on hypothetical floodplain restoration, CM5 implementation could result in periodic inundation of up to 142 acres of modeled western yellow-billed cuckoo habitat (17 acres of breeding habitat, 125 acres of migratory habitat). Inundation of restored floodplains is not expected to affect western yellow-billed cuckoo or its habitat adversely because the cuckoo breeding period is outside the period the floodplains would likely be inundated, and periodic inundation of floodplains is expected to restore a more natural flood regime in support of riparian vegetation types that provide nesting and migratory habitat for western yellow-billed cuckoo. The overall effect of seasonal inundation in existing riparian natural communities is likely to be beneficial for western yellow-billed cuckoo, because, historically, flooding was the main natural disturbance regulating ecological processes in riparian areas, and flooding promotes the germination and establishment of many native riparian plants.
**NEPA Effects:** Periodic effects of inundation would not have an adverse on yellow-billed cuckoo if they were to establish as breeders in the study area, because flooding is expected to occur outside of the breeding season.

**CEQA Conclusion:** Periodic effects of inundation would have a less-than-significant impact on yellow-billed cuckoos if they were to establish as breeders in the study area, because flooding is expected to occur outside of the breeding season.

### White-Tailed Kite

This section describes the effects of Alternative 1B, including water conveyance facilities construction and implementation of other conservation components, on white-tailed kite. The habitat model used to assess impacts on white-tailed kite includes nesting habitat and foraging habitat. Most white-tailed kites in the Sacramento Valley are found in oak and cottonwood riparian forests, valley oak woodlands, or other groups of trees and are usually associated with compatible foraging habitat for the species in patches greater than 1,500 square meters (Erichsen et al. 1996). Modeled foraging habitat for white-tailed kite consists of pasture and hay crops, compatible row and grain crops and natural vegetation such as seasonal wetlands and annual grasslands (Erichsen 1995).

Construction and restoration associated with Alternative 1B conservation measures would result in both temporary and permanent losses of white-tailed kite modeled habitat as indicated in Table 12-1B-41. The majority of the losses would take place over an extended period of time as tidal marsh is restored in the study area. Although restoration for the loss of nesting and foraging habitat would be initiated in the same timeframe as the losses, it could take one or more decades (for nesting habitat) for restored habitats to replace the functions of habitat lost. This time lag between impacts and restoration of habitat function would be minimized by specific requirements of AMM18 Swainson’s Hawk and White-Tailed Kite, including the planting of mature trees in the near-term time period. Full implementation of Alternative 1B would also include the following biological objectives over the term of the BDCP to benefit the white-tailed kite (BDCP Chapter 3, Conservation Strategy).

- Restore or create at least 5,000 acres of valley/foothill riparian natural community, with at least 3,000 acres occurring on restored seasonally inundated floodplain (Objective VFRNC1.1, associated with CM7).
- Protect at least 750 acres of existing valley/foothill riparian natural community in CZ 7 by year 10 (Objective VFRNC1.2, associated with CM3).
- Protect at least 8,000 acres of grassland with at least 2,000 acres protected in CZ 1, at least 1,000 acres protected in CZ 8, at least 2,000 acres protected in CZ 11, and the remainder distributed among Czs 1, 2, 4, 5, 7, 8, and 11 (Objective GNC1.1, associated with CM3).
- Restore at least 2,000 acres of grasslands (Objective GNC1.2, associated with CM8).
- Protect at least 150 acres of alkali seasonal wetland and at least 600 acres of existing vernal pool complex in Czs 1, 8, and/or 11 (Objectives ASWNC1.1 and VPNC1.1, associated with CM3).
- Protect and enhance at least 8,100 acres of managed wetland, at least 1,500 acres of which are in the Grizzly Island Marsh Complex (Objective MWNC1.1, associated with CM3).
- Increase prey availability and accessibility for grassland-foraging species (Objectives ASWNC2.4, VPNC2.5, and GNC2.4, associated with CM11).
- Protect at least 48,625 acres of cultivated lands that provide suitable habitat for covered and other native wildlife species (Objective CLNC1.1, associated with CM3).
- Plant and maintain native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SH2.1, associated with CM11).
- Maintain and protect the small patches of important wildlife habitats associated with cultivated lands within the reserve system including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Objective CLNC1.3, associated with CM3).
- Establish 20- to 30- foot-wide hedgerows along fields and roadsides to promote prey populations throughout protected cultivated lands (Objective SH2.2, associated with CM11).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance these natural communities for the species and implementation of AMM1–AMM7 and AMM18 Swainson’s Hawk and White-tailed Kite, impacts on white-tailed kite would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

*a* See Appendix 12E for detailed breakdown of conservation measure effects over the BDCP’s near-term and late long-term timeframes.

*b* See discussion below for a description of applicable CMs.

*c* LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

*d* Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

NT = near-term

LLT = late long-term

NA = not applicable
Impact BIO-100: Loss or Conversion of Habitat for and Direct Mortality of White-Tailed Kite

Alternative 1B conservation measures would result in the combined permanent and temporary loss of up to 69,935 acres of modeled habitat (707 acres of nesting habitat and 69,388 acres of foraging habitat) for white-tailed kite (Table 12-1B-41). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass fisheries improvements (CM2), tidal habitat restoration (CM4), floodplain restoration (CM5), riparian restoration, (CM7), grassland restoration (CM8), vernal pool and wetland restoration (CM9), nontidal marsh restoration (CM10), and construction of conservation hatcheries (CM18). Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, could result in local habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could affect white-tailed kite modeled habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.

- **CM1 Water Facilities and Operation:** Construction of Alternative 1B water conveyance facilities would result in the combined permanent and temporary loss of up to 79 acres of white-tailed kite nesting habitat (40 acres of permanent loss and 39 acres of temporary loss). The habitat would be removed at multiple locations from the north Delta to the east Delta and in the vicinity of Clifton Court Forebay. Almost all of the losses would occur on the borders of waterways. In the north Delta, most of the permanent loss would occur where Intakes 1–5 encroach on the Sacramento River's east bank between Freeport and Courtland. The riparian areas here are very small patches, some dominated by valley oak and others by nonnative trees and scrub vegetation. Other small patches or narrow bands of riparian vegetation dominated by valley oak, willow, cottonwood or mixed brambles would be permanently removed by canal construction adjacent to Intake 1, between Intakes 2 and 4, and just south of Lambert Road. In the east Delta, small permanent losses would occur from canal construction just south of Twin Cities Road and just north of Walnut Grove Road. The temporary riparian losses would occur at the intake sites along the Sacramento River and at temporary siphon work areas where the canal would cross Beaver Slough, Hog Slough, Sycamore Slough, White Slough, Disappointment Slough, Railroad Canal, and Middle River just south of Victoria Canal.

In addition, 15,069 acres of foraging habitat would be removed (5,475 acres of permanent loss, 9,594 acres of temporary loss; Table 12-1B-41). The foraging habitat losses would occur at various locations along the new canal route from the construction of the canal and the associated borrow and spoil sites and at the intake sites along the Sacramento River. Permanent and temporary losses of foraging habitat would also occur at the new forebay site just south of Clifton Court Forebay and associated borrow and spoil sites. There are no occurrences of white-tailed kite that overlap with the CM1 construction footprint. However, the implementation of **AMM18 Swainson's Hawk and White-Tailed Kite** would minimize effects on white-tailed kites if they were to nest within or adjacent to the construction footprint. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 1B construction locations.

- **CM2 Yolo Bypass Fisheries Enhancement:** Construction of the Yolo bypass fisheries enhancement would result in the combined permanent and temporary loss of up to 170 acres of nesting habitat (82 acres of permanent loss, 88 acres of temporary loss) in the Yolo Bypass in CZ 2. In addition, 1,525 acres of foraging habitat would be removed (1,008 acres of permanent loss, 516 acres of temporary loss). Activities through CM2 could involve excavation and grading in valley/foothill riparian areas to improve passage of fish through the bypasses. Most of the
riparian losses would occur at the north end of Yolo Bypass where major fish passage improvements are planned. Excavation to improve water movement in the Toe Drain and in the Sacramento Weir would also remove white-tailed kite habitat. The loss is expected to occur during the first 10 years of Alternative 1B implementation.

- **CM4 Tidal Natural Communities Restoration:** Tidal habitat restoration site preparation and inundation would permanently remove an estimated 383 acres of white-tailed kite nesting habitat and 41,625 acres of foraging habitat. The majority of the acres lost would consist of cultivated lands in CZs 1, 2, 4, 5, 6, and/or 7. Grassland losses would likely occur in the vicinity of Cache Slough, on Decker Island in the West Delta ROA, on the upslope fringes of Suisun Marsh, and along narrow bands adjacent to waterways in the South Delta ROA. Tidal restoration would directly impact and fragment grassland just north of Rio Vista in and around French and Prospect Islands, and in an area south of Rio Vista around Threemile Slough. Losses of alkali seasonal wetland complex habitat would likely occur in the south end of the Yolo Bypass and on the northern fringes of Suisun Marsh. The conversion of cultivated lands to tidal wetlands over fairly broad areas within the tidal restoration footprints could result in the removal or abandonment of nesting territories that occur within or adjacent to the restoration areas. Trees would not be actively removed but tree mortality would be expected over time as areas became tidally inundated. Depending on the extent and value of remaining habitat, this could reduce the local nesting population.

- **CM5 Seasonally Inundated Floodplain Restoration:** Construction of setback levees to restore seasonally inundated floodplain and riparian restoration actions would remove approximately 75 acres of white-tailed kite nesting habitat (42 acres of permanent loss, 33 acres of temporary loss) and 2,675 acres of foraging habitat (1,706 acres of permanent loss, 968 acres of temporary loss). These losses would be expected after the first 10 years of Alternative 1B implementation along the San Joaquin River and other major waterways in CZ 7.

- **CM7 Riparian Natural Community Restoration:** Riparian restoration would permanently remove approximately 971 acres of white-tailed kite foraging habitat as part of tidal restoration and 3,991 acres as part of seasonal floodplain restoration through CM7.

- **CM8 Grassland Natural Community Restoration:** Restoration of grassland is expected to be implemented on agricultural lands and would result in the conversion of 1,849 acres of white-tailed kite agricultural foraging habitat to grassland foraging habitat in CZs 1, 2, 4, 5, 7, 8, and 11. If agricultural lands supporting higher value foraging habitat than the restored grassland were removed, there would be a loss of white-tailed kite foraging habitat value.

- **CM10 Nontidal Marsh Restoration:** Restoration and creation of nontidal freshwater marsh (CM10) would result in the permanent conversion of 1,440 acres of cultivated lands to nontidal marsh in CZ 2 and CZ 4. This would not result in a loss of foraging habitat as both natural communities are foraging habitat for white-tailed kite. Small patches of riparian vegetation that support White-tailed kite nesting habitat may develop along the margins of restored nontidal marsh restoration would also provide foraging habitat for the species.

- **CM11 Natural Communities Enhancement and Management:** Habitat management- and enhancement-related activities could disturb white-tailed kite nests if they were present near work sites. A variety of habitat management actions that are designed to enhance wildlife values in BDCP-protected habitats may result in localized ground disturbances that could temporarily remove small amounts of white-tailed kite habitat and reduce the functions of habitat until restoration is complete. Ground-disturbing activities, such as removal of nonnative vegetation...
and road and other infrastructure maintenance, are expected to have minor effects on available
white-tailed kite habitat and are expected to result in overall improvements to and maintenance
of habitat values over the term of the BDCP. These effects cannot be quantified, but are expected
to be minimal and would be avoided and minimized by the AMMs listed below. CM11 would also
include the construction of recreational-related facilities including trails, interpretive signs, and
picnic tables (BDCP Chapter 4, Covered Activities and Associated Federal Actions). The
construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be
placed on existing, disturbed areas when and where possible. However, approximately 50 acres
of white-tailed kite grassland foraging habitat would be lost from the construction of trails and
facilities.

- **CM18 Conservation Hatcheries**: Implementation of CM18 would remove up to 35 acres of high-
white-tailed kite foraging habitat for the development of a delta and longfin smelt conservation
hatchery in CZ 1. The loss is expected to occur during the first 10 years of Alternative 1B
implementation.

Permanent and temporary white-tailed kite nesting habitat losses from the above conservation
measures, would primarily consist of small, fragmented riparian stands. Temporarily affected
nesting habitat would be restored as riparian habitat within 1 year following completion of
construction activities. The restored riparian habitat would require 1 to several decades to
functionally replace habitat that has been affected and for trees to attain sufficient size and
structure suitable for nesting by white-tailed kite. **AMM18 Swainson’s Hawk and White-Tailed
Kite** contains actions described below to reduce the effect of temporal loss of nesting habitat,
including the transplantsing of mature trees and planting of trees near high-value foraging
habitat. The functions of agricultural and grassland communities that provide foraging habitat
for white-tailed kite are expected to be restored relatively quickly.

- **Operations and Maintenance**: Postconstruction operation and maintenance of the above-ground
water conveyance facilities and restoration infrastructure could result in ongoing but periodic
disturbances that could affect white-tailed kite use of the surrounding habitat. Maintenance
activities would include vegetation management, levee and structure repair, and re-grading of
roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7
and **AMM18 Swainson’s Hawk and White-Tailed Kite** in addition to conservation actions as
described below.

- **Injury and Direct Mortality**: Construction-related activities would not be expected to result in
direct mortality of adult or fledged white-tailed kite if they were present in the Plan Area,
because they would be expected to avoid contact with construction and other equipment.
However, if white-tailed kite were to nest in the construction area, construction-related
activities, including equipment operation, noise and visual disturbances could affect nests or
lead to their abandonment, potentially resulting in mortality of eggs and nestlings. These effects
would be avoided and minimized with the incorporation of **AMM18 Swainson’s Hawk and White-
Tailed Kite** into the BDCP.

The following paragraphs summarize the combined effects discussed above and describe other
BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also
included.
Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the effect of construction would not be adverse under NEPA. The Plan would remove 479 acres (352 acres of permanent loss, 127 acres of temporary loss) of white-tailed kite nesting habitat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 79 acres), and implementing other conservation measures (CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, and CM5 Seasonally Inundated Floodplain Restoration—400 acres). In addition, 24,308 acres of white-tailed kite foraging habitat would be removed or converted in the near-term (CM1, 15,069 acres; CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, CM5 Seasonally Inundated Floodplain Restoration, CM7 Riparian Natural Community Restoration, CM8 Grassland Natural Community Restoration, CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration, CM11 Natural Communities Enhancement and Management and CM18 Conservation Hatcheries—9,239 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 and that are identified in the biological goals and objectives for white-tailed kite in Chapter 3 of the BDCP would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat for nesting habitat, 1:1 protection for foraging habitat. Using these ratios would indicate that 79 acres of nesting habitat should be restored/created and 79 acres should be protected to mitigate the CM1 losses of white-tailed kite nesting habitat. In addition, 15,069 acres of foraging habitat should be protected to compensate for the CM1 losses of white-tailed kite foraging habitat. The near-term effects of other conservation actions would remove 400 acres of modeled nesting habitat, and therefore require 400 acres of protection of nesting habitat. Similarly, the near-term effects of other conservation actions would result in the loss or conversion of 9,239 acres of modeled foraging habitat, and therefore require 9,239 acres of protection of foraging habitat using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection of nesting habitat; 1:1 for protection of foraging habitat).

The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of valley/foothill riparian natural community, protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, protecting 4,800 acres of managed wetland natural community, protecting 15,400 acres of non-rice cultivated lands, protecting 900 acres of rice or rice equivalent habitat, and restoring 19,150 acres of tidal wetlands (Table 3-4 in Chapter 3). These conservation actions are associated with CM3, CM4, CM7, and CM8 and would occur in the same timeframe as the construction and early restoration losses.

The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, Conservation Strategy). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for the species. White-tailed kite is excluded from narrow bands of riparian vegetation by Swainson’s hawks and therefore requires wide patches of nesting habitat where its range overlaps with Swainson’s hawk. The distribution and abundance of potential white-tailed kite nest trees would be increased by planting and maintaining native trees along roadsides and field borders.
within protected cultivated lands at a rate of one tree per 10 acres (Objective SWHA2.1). In addition, small but essential nesting habitat associated with cultivated lands would also be maintained and protected such as isolated trees, tree rows along field borders or roads, or small clusters of trees in farmyards or at rural residences (Objective CLNC1.3).

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide foraging habitat for white-tailed kite and reduce the effects of current levels of habitat fragmentation. Small mammal populations would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4).

Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Remnant patches of grassland or other uncultivated areas would also be protected and maintained as part of the cultivated lands reserve system which would provide additional foraging habitat and a source of rodent prey that could recolonize cultivated fields (Objective CLNC1.3). The protection of managed wetlands (including upland grassland components) that dry during the spring would also serve as foraging habitat for white-tailed kite as prey species recolonize the fields (Objective MWNC1.1). In addition, the restoration of 19,150 acres of tidal natural communities, including transitional uplands would provide high-value foraging habitat for the white-tailed kite. At least 15,400 acres of cultivated lands that provide habitat for covered and other native wildlife species would be protected in the near-term time period (Objective CLNC1.1). These biological goals and objectives would inform the near-term protection and restoration efforts and represent performance standards for considering the effectiveness of restoration actions. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on white-tailed kite foraging habitat, as well as mitigate the near-term effects of the other conservation measures.

The 750 acres of protection and 800 acres of restoration contained in the near-term Plan goals satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1 and other near-term impacts on white-tailed kite nesting habitat. The 800 acres of restored riparian habitat would be initiated in the near-term to offset the loss of modeled nesting habitat, but would require one to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by white-tailed kites. This time lag between the removal and restoration of nesting habitat could have a substantial impact on white-tailed kite in the near-term time period. Nesting habitat is limited throughout much of the Plan Area, consisting mainly of intermittent riparian, isolated trees, small groves, tree rows along field borders, roadside trees, and ornamental trees near rural residences. The removal of nest trees or nesting habitat would further reduce this limited resource and could reduce or restrict the number of active white-tailed kite nests within the Plan Area until restored riparian habitat is sufficiently developed.

AMM18 Swainson's Hawk and White-Tailed Kite would implement a program to plant large mature trees, including transplanting trees scheduled for removal. These would be supplemented with additional saplings and would be expected to reduce the temporal effects of loss of nesting habitat. The plantings would occur prior to or concurrent with (in the case of transplanting) the loss of trees. In addition, at least five trees (5-gallon container size) would be planted within the BDCP reserve system for every tree 20 feet or taller anticipated to be removed by construction during the near-
term period. A variety of native tree species would be planted to provide trees with differing growth rates, maturation, and life span. Trees would be planted within the BDCP reserve system in areas that support high value foraging habitat in dumps of at least three trees each at appropriate sites within or adjacent to conserved cultivated lands, or they could be incorporated as a component of the riparian restoration (CM5, CM7) where they are in close proximity to suitable foraging habitat. Replacement trees that were incorporated into the riparian restoration would not be clustered in a single region of the Plan Area, but would be distributed throughout the lands protected as foraging habitat for white-tailed kite. With this program in place, Alternative 1B would not have a substantial adverse effect on white-tailed kite in the near-term timeframe, either through direct mortality or through habitat modifications.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.

**Late Long-Term Timeframe**

The study area supports approximately 14,069 acres of modeled nesting habitat and 507,922 acres of modeled foraging habitat for white-tailed kite. Alternative 1A as a whole would result in the permanent loss of and temporary effects on 707 acres of potential nesting habitat (5% of the potential nesting habitat in the study area) and the loss or conversion of 69,388 acres of foraging habitat (14% of the foraging habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures.

The Plan includes conservation commitments through CM3 Natural Communities Protection and Restoration, CM4 Tidal Natural Communities Restoration, CM5 Seasonally Inundated Floodplain Restoration, CM7 Riparian Natural Community Restoration, and CM8 Grassland Natural Community Restoration to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill riparian natural community, protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex, protect 8,100 acres of managed wetland, protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species, and restore at least 65,000 acres of tidal wetlands (Table 3-4 in Chapter 3).

The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, Conservation Strategy). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for the species. White-tailed kite is excluded from narrow bands of riparian vegetation by Swainson’s hawks and therefore requires wide patches of nesting habitat where its range overlaps with Swainson’s hawk. The distribution and abundance of potential white-tailed kite nest trees would be increased by planting and maintaining native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SWHA2.1). In addition, small but essential nesting habitat associated with cultivated lands would also be maintained and
protected such as isolated trees, tree rows along field borders or roads, or small clusters of trees in
farmyards or at rural residences (Objective CLNC1.3).

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1
and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali
seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous
matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would
provide foraging habitat for white-tailed kite and reduce the effects of current levels of habitat
fragmentation. Small mammal populations would also be increased on protected lands, enhancing
the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4).
Foraging opportunities would also be improved by enhancing prey populations through the
establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected
cultivated lands (Objective SWHA2.2). Remnant patches of grassland or other uncultivated areas
would also be protected and maintained as part of the cultivated lands reserve system which would
provide additional foraging habitat and a source of rodent prey that could recolonize cultivated
fields (Objective CLNC1.3). The protection of managed wetlands (including upland grassland
components) that dry during the spring would also serve as foraging habitat for white-tailed kite as
prey species recolonize the fields (Objective MWNC1.1). In addition, the restoration of at least
65,000 acres of tidal natural communities, including transitional uplands would provide high-value
foraging habitat for the white-tailed kite. At least 45,405 acres of cultivated lands that provide
foraging habitat for white-tailed kite would be protected by the late long-term time period
(Objective CLNC1.1).

The BDCP’s beneficial effects analysis (BDCP Chapter 5, Section 5.6, Effects on Covered Wildlife and
Plant Species) estimates that the restoration and protection actions discussed above could result in
the restoration of 3,800 acres and the protection of 570 acres of nesting habitat and the restoration
of 49,875 acres and the protection of 2,050 acres of foraging habitat for white-tailed kite.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2
Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention
Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and
Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged
Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or
minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are
described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.

**NEPA Effects:** The loss of white-tailed kite habitat and potential for direct mortality of this special-
status species under Alternative 1B would represent an adverse effect in the absence of other
conservation actions. However, with habitat protection and restoration associated with CM3, CM5,
CM7, CM8, CM9, and CM11, guided by biological goals and objectives and by AMM1–AMM7 and
AMM18 Swainson’s Hawk and White-Tailed Kite, which would be in place throughout the
construction period, the effects of habitat loss and potential mortality on white-tailed kite under
Alternative 1B would not be adverse.

**CEQA Conclusion:**

**Near-Term Timeframe**

Because the water conveyance facilities construction (CM1) is being evaluated at the project level,
the near-term BDCP conservation strategy has been evaluated to determine whether it would
provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the effect of construction would be less than significant under CEQA. The Plan would remove 479 acres (352 acres of permanent loss, 127 acres of temporary loss) of white-tailed kite nesting habitat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 79 acres), and implementing other conservation measures (CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, and CM5 Seasonally Inundated Floodplain Restoration—400 acres). In addition, 24,308 acres of white-tailed kite foraging habitat would be removed or converted in the near-term (CM1, 15,069 acres; CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, CM5 Seasonally Inundated Floodplain Restoration, CM7 Riparian Natural Community Restoration, CM8 Grassland Natural Community Restoration, CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration, CM11 Natural Communities Enhancement and Management and CM18 Conservation Hatcheries—9,239 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 and that are identified in the biological goals and objectives for white-tailed kite in Chapter 3 of the BDCP would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat for nesting habitat, 1:1 protection for foraging habitat. Using these ratios would indicate that 79 acres of nesting habitat should be restored/created and 79 acres should be protected to mitigate the CM1 losses of white-tailed kite nesting habitat. In addition, 15,069 acres of foraging habitat should be protected to compensate for the CM1 losses of white-tailed kite foraging habitat. The near-term effects of other conservation actions would remove 400 acres of modeled nesting habitat, and therefore require 400 acres of protection of nesting habitat. Similarly, the near-term effects of other conservation actions would result in the loss or conversion of 9,239 acres of modeled foraging habitat, and therefore require 9,239 acres of protection of foraging habitat using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection of nesting habitat; 1:1 for protection of foraging habit).

The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of valley/foothill riparian natural community, protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, protecting 4,800 acres of managed wetland natural community, protecting 15,400 acres of non-rice cultivated lands, protecting 900 acres of rice or rice equivalent habitat, and restoring 19,150 acres of tidal wetlands (Table 3-4 in Chapter 3). These conservation actions are associated with CM3, CM4, CM7, and CM8 and would occur in the same timeframe as the construction and early restoration losses.

The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, Conservation Strategy). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for the species. White-tailed kite is excluded from narrow bands of riparian vegetation by Swainson’s hawks and therefore requires wide patches of nesting habitat where its range overlaps with Swainson's hawk. The distribution and abundance of potential white-tailed kite nest trees would be increased by planting and maintaining native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SWHA2.1). In addition, small but essential nesting habitat associated with cultivated lands would also be maintained and protected such as isolated trees, tree rows along field borders or roads, or small clusters of trees in farmyards or at rural residences (Objective CLNC1.3).
Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide foraging habitat for white-tailed kite and reduce the effects of current levels of habitat fragmentation. Small mammal populations would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Remnant patches of grassland or other uncultivated areas would also be protected and maintained as part of the cultivated lands reserve system which would provide additional foraging habitat and a source of rodent prey that could recolonize cultivated fields (Objective CLNC1.3). The protection of managed wetlands (including upland grassland components) that dry during the spring would also serve as foraging habitat for white-tailed kite as prey species recolonize the fields (Objective MWNC1.1). In addition, the restoration of 19,150 acres of tidal natural communities, including transitional uplands would provide high-value foraging habitat for the white-tailed kite. At least 15,400 acres of cultivated lands that provide habitat for covered and other native wildlife species would be protected in the near-term time period (Objective CLNC1.1). These biological goals and objectives would inform the near-term protection and restoration efforts and represent performance standards for considering the effectiveness of restoration actions. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on white-tailed kite foraging habitat, as well as mitigate the near-term effects of the other conservation measures.

The 750 acres of protection and 800 acres of restoration contained in the near-term Plan goals satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1 and other near-term impacts on white-tailed kite nesting habitat. The 800 acres of restored riparian habitat would be initiated in the near-term to offset the loss of modeled nesting habitat, but would require one to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by white-tailed kites. This time lag between the removal and restoration of nesting habitat could have a substantial impact on white-tailed kite in the near-term time period. Nesting habitat is limited throughout much of the Plan Area, consisting mainly of intermittent riparian, isolated trees, small groves, tree rows along field borders, roadside trees, and ornamental trees near rural residences. The removal of nest trees or nesting habitat would further reduce this limited resource and could reduce or restrict the number of active white-tailed kite nests within the Plan Area until restored riparian habitat is sufficiently developed.

**AMM18 Swainson’s Hawk and White-Tailed Kite** would implement a program to plant large mature trees, including transplanting trees scheduled for removal. These would be supplemented with additional saplings and would be expected to reduce the temporal effects of loss of nesting habitat. The plantings would occur prior to or concurrent with (in the case of transplanting) the loss of trees. In addition, at least five trees (5-gallon container size) would be planted within the BDCP reserve system for every tree 20 feet or taller anticipated to be removed by construction during the near-term period. Of the replacement trees planted, a variety of native tree species would be planted to provide trees with differing growth rates, maturation, and life span. Trees would be planted within the BDCP reserve system in areas that support high value foraging habitat in clumps of at least three trees each at appropriate sites within or adjacent to conserved cultivated lands, or they could be
incorporated as a component of the riparian restoration (CM5, CM7) where they are in close proximity to suitable foraging habitat. Replacement trees that were incorporated into the riparian restoration would not be clustered in a single region of the Plan Area, but would be distributed throughout the lands protected as foraging habitat for white-tailed kite. With this program in place, Alternative 1B would not have a substantial adverse effect on white-tailed kite in the near-term timeframe, either through direct mortality or through habitat modifications.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.

**Late Long-Term Timeframe**

The study area supports approximately 14,069 acres of modeled nesting habitat and 507,922 acres of modeled foraging habitat for white-tailed kite. Alternative 1B as a whole would result in the permanent loss of and temporary effects on 707 acres of potential nesting habitat (5% of the potential nesting habitat in the study area) and the loss or conversion of 69,388 acres of foraging habitat (14% of the foraging habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures.

The Plan includes conservation commitments through CM3 Natural Communities Protection and Restoration, CM4 Tidal Natural Communities Restoration, CM5 Seasonally Inundated Floodplain Restoration, CM7 Riparian Natural Community Restoration, and CM8 Grassland Natural Community Restoration to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill riparian natural community, protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex, protect 8,100 acres of managed wetland, protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species, and restore at least 65,000 acres of tidal wetlands (Table 3-4 in Chapter 3).

The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, Conservation Strategy). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for the species. White-tailed kite is excluded from narrow bands of riparian vegetation by Swainson’s hawks and therefore requires wide patches of nesting habitat where its range overlaps with Swainson’s hawk. The distribution and abundance of potential white-tailed kite nest trees would be increased by planting and maintaining native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SWHA2.1). In addition, small but essential nesting habitat associated with cultivated lands would also be maintained and protected such as isolated trees, tree rows along field borders or roads, or small clusters of trees in farmyards or at rural residences (Objective CLNC1.3).

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous
matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide foraging habitat for white-tailed kite and reduce the effects of current levels of habitat fragmentation. Small mammal populations would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Remnant patches of grassland or other uncultivated areas would also be protected and maintained as part of the cultivated lands reserve system which would provide additional foraging habitat and a source of rodent prey that could recolonize cultivated fields (Objective CLNC1.3). The protection of managed wetlands (including upland grassland components) that dry during the spring would also serve as foraging habitat for white-tailed kite as prey species recolonize the fields (Objective MWNC1.1). In addition, the restoration of at least 65,000 acres of tidal natural communities, including transitional uplands would provide high-value foraging habitat for the white-tailed kite. At least 45,405 acres of cultivated lands that provide foraging habitat for white-tailed kite would be protected by the late long-term time period (Objective CLNC1.1).

The BDCP’s beneficial effects analysis (BDCP Chapter 5, Section 5.6, Effects on Covered Wildlife and Plant Species) estimates that the restoration and protection actions discussed above could result in the restoration of 3,800 acres and the protection of 570 acres of nesting habitat and the restoration of 49,875 acres and the protection of 2,050 acres of foraging habitat for white-tailed kite.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.

Considering Alternative 1B’s protection and restoration provisions, which would provide acreages of new or enhanced habitat in amounts greater than necessary to compensate for the time lag of restoring riparian and foraging habitats lost to construction and restoration activities, and with implementation of AMM1–AMM7 and AMM18 Swainson’s Hawk and White-Tailed Kite, the loss of habitat or direct mortality through implementation of Alternative 1B would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. In particular, 95% of the loss of foraging habitat effects involve the conversion of one habitat type to another form of suitable foraging habitat. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on white-tailed kite.

Impact BIO-101: Effects on White-Tailed Kite Associated with Electrical Transmission Facilities

New transmission lines would increase the risk that white-tailed kites could be subject to power line strikes and/or electrocution, which could result in injury or mortality of individuals. This species would be at low risk of bird strike mortality based on its general maneuverability, its keen eyesight, and lack of flocking behavior (BDCP Attachment 5J.C, Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines). AMM20 Greater Sandhill Crane would further reduce any potential effects.
**NEPA Effects:** New transmission lines would minimally increase the risk for white-tailed kite power line strikes. However, the species would be at a low risk of bird strike mortality based on its general maneuverability, its keen eyesight and lack of flocking behavior. With the implementation of AMM20 Greater Sandhill Crane the potential effect of the construction of new transmission lines on white-tailed kite would not be adverse.

**CEQA Conclusion:** New transmission lines would increase the risk for white-tailed kite power line strikes and/or electrocution. However, the species would be at a low risk of bird strike mortality based on its general maneuverability, its keen eyesight and lack of flocking behavior. AMM20 Greater Sandhill Crane would further reduce any potential impact of the construction of new transmission lines on white-tailed kite to a less-than-significant level.

**Impact BIO-102: Indirect Effects of Plan Implementation on White-Tailed Kite**

White-tailed kite nesting habitat within the vicinity of proposed construction areas could be indirectly affected by construction activities. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane, Table 4), although there are no available data to determine the extent to which these noise levels could affect white-tailed kite. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 1,300 feet from the construction edge. If white-tailed kite were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. AMM18 Swainson’s Hawk and White-Tailed Kite would require preconstruction surveys, and if detected, 200 yard no disturbance buffers would be established around active nests. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect white-tailed kite. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint. If white-tailed kite habitat were to be affected, measures to prevent runoff from the construction area and negative effects of dust on active nests would be implemented.

**Methylmercury Exposure:** Covered activities have the potential to exacerbate bioaccumulation of mercury in avian species, including white-tailed kite. Marsh (tidal and nontidal) and floodplain restoration also have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury (see BDCP Chapter 3, Conservation Strategy, for details of restoration). Increased methylmercury associated with natural community and floodplain restoration may indirectly affect white-tailed kite (see BDCP Appendix 5.D, Contaminants). However, the potential mobilization or creation of methylmercury within the study area varies with site-specific conditions and would need to be assessed at the project level. CM12 Methylmercury Management includes provisions for project-specific Mercury Management Plans. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would be available to address the uncertainty of methylmercury levels in restored tidal marsh and potential impacts on white-tailed kite.
**Selenium Exposure:** Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher levels of selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including white-tailed kite. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4–CM5) would lead to adverse effects on white-tailed kite.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on white-tailed kite from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of *AMM27 Selenium Management* (BDCP Appendix 3.C, *Avoidance and Minimization Measures*) which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

**NEPA Effects:** Noise and visual disturbances from the construction of water conveyance facilities could reduce white-tailed kite use of modeled habitat adjacent to work areas. Moreover, operation
and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect white-tailed kite use of the surrounding habitat. Noise, potential spills of hazardous materials, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities under Alternative 1B would not have an adverse effect on white-tailed kite with the implementation of AMM1–AMM7, and AMM18 Swainson’s Hawk and White-Tailed Kite. Tidal habitat restoration could result in increased exposure of white-tailed kite to selenium. This effect would be addressed through the implementation of AMM27 Selenium Management which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. The indirect effects associated with noise and visual disturbances, potential spills of hazardous material, and increased exposure to selenium from Alternative 1B implementation would not have an adverse effect on white-tailed kite. Tidal habitat restoration is unlikely to have an adverse effect on white-tailed kite through increased exposure to methylmercury, as kites currently forage in tidal marshes where elevated methylmercury levels exist. However, it is unknown what concentrations of methylmercury are harmful to the species and the potential for increased exposure varies substantially within the study area. Site-specific restoration plans in addition to monitoring and adaptive management, described in CM12 Methylmercury Management, would address the uncertainty of methylmercury levels in restored tidal marsh. The site-specific planning phase of marsh restoration would be the appropriate place to assess the potential for risk of methylmercury exposure for white-tailed kite, once site specific sampling and other information could be developed.

CEQA Conclusion: Noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities under Alternative 1B would have a less-than-significant impact on white-tailed kite with the implementation of AMM1B Swainson’s Hawk and White-Tailed Kite, and AMMs1–7. Tidal habitat restoration could result in increased exposure of white-tailed kite to selenium. This effect would be addressed through the implementation of AMM27 Selenium Management which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of white-tailed kite to methylmercury. However, it is unknown what concentrations of methylmercury are harmful to this species. CM12 Methylmercury Management includes provisions for project-specific Mercury Management Plans. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12, would better inform potential impacts and address the uncertainty of methylmercury levels in restored tidal marsh in the study area on white-tailed kite. With these measures in place, the indirect effects associated with noise and visual disturbances, potential spills of hazardous material, and increased exposure to selenium from Alternative 1B implementation would have a less-than-significant impact on white-tailed kite.

Impact BIO-103: Periodic Effects of Inundation of White-Tailed Kite Habitat as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from Fremont Weir operations related to CM2 Yolo Bypass Fisheries Enhancement would increase the frequency and duration of inundation on approximately 48–82 acres of modeled white-tailed kite nesting habitat and 3,030–6,651 acres of modeled white-tailed kite foraging habitat (Table 12-1B-41). During inundation years, affected cultivated lands and grassland would not be available as foraging habitat until prey populations have re-inhabited
inundated areas. This would result in temporary periodic reduction in availability of foraging habitat. If late-season Fremont Weir operations were to preclude the planting of some crop types, there could be a further loss of foraging habitat value if the crop type that would have been planted would provide greater foraging habitat value than the fallowed fields. No known white-tailed kite nest sites would be affected, and increased periodic flooding is not expected to cause any adverse effect on nest sites that may be within the inundation area because existing trees already withstand floods in the area, the increase in inundation frequency and duration is expected to remain within the range of tolerance of riparian trees, and any nest sites would be located above floodwaters.

Based on hypothetical floodplain restoration, CM5 implementation could result in periodic inundation of up to approximately 230 acres of modeled white-tailed kite nesting habitat and 7,402 acres of modeled white-tailed kite foraging habitat (Table 12-1B-41). Inundation of foraging habitat could result in a periodic reduction of available foraging habitat due to the reduction in available prey. Following draw-down, inundated habitats are expected to recover and provide suitable foraging conditions until the following inundation period. Thus, this is considered a periodic impact that is unlikely to affect white-tailed kite distribution and abundance, or foraging use of the Plan Area.

Periodic inundation of floodplains (through CM2 and CM5) would be expected to restore a more natural flood regime in support of riparian vegetation types that support white-tailed kite nesting habitat. No adverse effects of inundation on white-tailed kite riparian habitat are expected because valley/foothill riparian vegetation is expected to benefit from seasonal inundation.

**NEPA Effects:** Although foraging habitat would be periodically unavailable to white-tailed kite because of CM2 and CM5 implementation, inundated habitats are expected to recover following draw-down. Any effects are considered short-term and would not result in an adverse effect.

**CEQA Conclusion:** Although foraging habitat would be periodically unavailable to white-tailed kite because of CM2 and CM5 implementation, inundated habitats are expected to recover following draw-down. Any effects are considered short-term and would be expected to have a less-than-significant impact on white-tailed kite.

### Yellow-Breasted Chat

This section describes the effects of Alternative 1B, including water conveyance facilities construction and implementation of other conservation components, on yellow-breasted chat. Yellow-breasted chat modeled habitat includes suitable nesting and migratory habitat as those plant alliances from the valley/foothill riparian modeled habitat that contain a shrub component and an overstory component. Primary nesting and migratory habitat is qualitatively distinguished from secondary habitat in Delta areas as those plant associations that support a greater percentage of a suitable shrub cover, particularly blackberry, and California wild rose, and have an open to moderately dense overstory canopy, using data from Hickson and Keeler-Wolf (2007). No distinction is made between primary and secondary habitat for Suisun Marsh/Yolo Basin habitats because supporting information is lacking. For this reason, the effects analysis only provides the breakdown between primary and secondary habitat in the habitat loss totals and associated tables, and does not provide this breakdown in the text by activity or effect type.

Construction and restoration associated with Alternative 1B conservation measures would result in both temporary and permanent losses of yellow-breasted chat modeled habitat as indicated in Table 12-1B-42. Full implementation of Alternative 1B would also include the following conservation
actions over the term of the BDCP to benefit the yellow-breasted chat (BDCP Chapter 3, Section 3.3, Biological Goals and Objectives).

- Restore or create at least 5,000 acres of valley/foothill riparian natural community, with at least 3,000 acres occurring on restored seasonally inundated floodplain (Objective VFRNC1.1, associated with CM7).
- Protect at least 750 acres of existing valley/foothill riparian natural community in CZ 7 by year 10 (Objective VFRNC1.2, associated with CM3).
- Restore, maintain and enhance structural heterogeneity with adequate vertical and horizontal overlap among vegetation components and over adjacent riverine channels, freshwater emergent wetlands, and grasslands (Objective VFRNC2.1, associated with CM7).
- Maintain at least 1,000 acres of early- to mid-successional vegetation with a well-developed understory of dense shrubs on restored seasonally inundated floodplain (Objective VFRNC2.2, associated with CM7).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance these natural communities for the species and implementation of AMM1–AMM7 and AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo, impacts on yellow-breasted chat would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

\(^a\) See Appendix 12E for detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

\(^b\) See discussion below for a description of applicable CMs.

\(^c\) LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

\(^d\) Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

**Impact BIO-104: Loss or Conversion of Habitat for and Direct Mortality of Yellow-Breasted Chat**

Alternative 1B conservation measures would result in the combined permanent and temporary loss of up to 817 acres of modeled nesting and migratory habitat for yellow-breasted chat (680 acres of permanent loss, 137 acres of temporary loss (Table 12-1B-42). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Fremont Weir/Yolo Bypass improvements (CM2), tidal habitat restoration (CM4), and floodplain restoration (CM5). Habitat enhancement and management activities (CM11), which would include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate yellow-breasted chat habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.
• **CM1 Water Facilities and Operation**: Construction of Alternative 1B conveyance facilities would result in the combined permanent and temporary loss of up 30 acres of primary habitat (9 acres of permanent loss, 21 acres of temporary loss). In addition, 22 acres of secondary habitat would be removed (10 acres of permanent loss, 12 acres of temporary loss) (Table 12-1B-42). The habitat would be removed at multiple locations from the north Delta to the east Delta and in the vicinity of Clifton Court Forebay. Almost all of the losses would occur on the borders of waterways. In the north Delta, most of the permanent loss would occur where Intakes 1–5 encroach on the Sacramento River’s east bank between Freeport and Courtland. The riparian areas here are very small patches, some dominated by valley oak and others by nonnative trees and scrub vegetation. In the east Delta, small permanent losses would occur from canal construction just south of Twin Cities Road and just north of Walnut Grove Road. A small area of riparian habitat (mostly blackberries) would be permanently removed in the south Delta at the new forebay construction site. The temporary riparian losses would occur at the intake sites along the Sacramento River and at temporary siphon work areas where the canal would cross Beaver Slough, Hog Slough, Sycamore Slough, White Slough, Disappointment Slough, Railroad Canal, and Middle River just south of Victoria Canal. Tunnel construction at Old River just south of Victoria Canal would also temporarily remove mixed willows and brambles. There are no occurrences of yellow-breasted chat that overlap with the CM1 construction footprint. The implementation of AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell’s Vireo, Western Yellow-Billed Cuckoo would minimize effects on yellow-breasted chat if they were to nest within or adjacent to the construction footprint. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 1B construction locations.

• **CM2 Yolo Bypass Fisheries Enhancement**: Construction would permanently remove approximately 83 acres and temporarily remove 88 acres of yellow-breasted chat habitat in the Yolo Bypass in CZ 2. The loss is expected to occur during the first 10 years of Alternative 1B implementation.

• **CM4 Tidal Natural Communities Restoration**: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 545 acres of modeled yellow-breasted chat habitat in CZ 1, 2, 6, and 11. This total is composed of an estimated 182 acres of primary nesting and migratory habitat, 349 acres of secondary nesting and migratory habitat, and 14 acres of nesting and migratory habitat in the Suisun Marsh and upper Yolo Bypass areas.

• **CM5 Seasonally Inundated Floodplain Restoration**: Construction of setback levees to restore seasonally inundated floodplain would permanently and temporarily remove approximately 49 acres of modeled yellow-breasted chat habitat in CZ 7. This total is comprised of 28 acres of primary nesting and migratory habitat and 21 acres of secondary nesting and migratory habitat. Based on the riparian habitat restoration assumptions, approximately 3,000 acres of valley/foothill riparian habitat would be restored as a component of seasonally inundated floodplain restoration actions. The actual number of acres that would be restored may differ from these estimates, depending on how closely the outcome of seasonally inundated floodplain restoration approximates the assumed outcome. Once this restored riparian vegetation has developed habitat functions, a portion of it would be suitable to support yellow-breasted chat habitat.

• **CM11 Natural Communities Enhancement and Management**: Habitat protection and management activities that could be implemented in protected yellow-breasted chat habitats would be expected to maintain and improve the functions of the habitat over the term of the BDCP.
Yellow-breasted chat would be expected to benefit from the increase in protected habitat, which would maintain conditions favorable for the chat's use of the Plan Area.

Habitat management- and enhancement-related activities could disturb yellow-breasted chat nests if they are present near work sites. Equipment operation could destroy nests, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell’s Vireo, Western Yellow-Billed Cuckoo would ensure that these activities do not result in direct mortality of yellow-breasted chat or other adverse effects.

Occupied habitat would be monitored to determine if there is a need to implement controls on brood parasites (brown-headed cowbird) or nest predators. If implemented, these actions would be expected to benefit the yellow-breasted chat by removing a potential stressor that could, if not addressed, adversely affect the stability of newly established populations.

A variety of habitat management actions included in CM11 Natural Communities Enhancement and Management that are designed to enhance wildlife values in restored riparian habitats may result in localized ground disturbances that could temporarily remove small amounts of yellow-breasted chat habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, are expected to have minor adverse effects on available yellow-breasted chat habitat and are expected to result in overall improvements to and maintenance of yellow-breasted chat habitat values over the term of the BDCP.

- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect Bell’s vireo and yellow warbler use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs and conservation actions as described below.

- Injury and Direct Mortality: Construction is not expected to result in direct mortality of yellow-breasted chat because adults and fledged young are expected to occur only in very small numbers and, if present, would avoid contact with construction and other equipment. If yellow-breasted chat were to nest in the vicinity of construction activities, equipment operation could destroy nests and noise and visual disturbances could lead to nest abandonment. AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell’s Vireo, Western Yellow-Billed Cuckoo would avoid and minimize this effect.

- Permanent and temporary habitat losses from the above CMs, would primarily consist of small, fragmented riparian stands in CZ 2–CZ 8 that do not provide high-value habitat for the species. Temporarily affected areas would be restored as riparian habitat within 1 year following completion of construction activities. Although the effects are considered temporary, the restored riparian habitat would require 5 years to several decades, for ecological succession to occur and for restored riparian habitat to functionally replace habitat that has been affected. The majority of the riparian vegetation to be temporarily removed is early- to mid-successional; therefore, the replaced riparian vegetation would be expected to have structural components comparable to the temporarily removed vegetation within the first 5 to 10 years after the initial restoration activities are complete.
The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

**Near-Term Timeframe**

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. The Plan would remove 521 acres of modeled habitat for yellow-breasted chat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 53 acres of modeled nesting and migratory habitat), and implementing other conservation measures (CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, and CM5 Seasonally Inundated Floodplain Restoration—468 acres of modeled nesting and migratory habitat). These habitat losses would primarily consist of small, fragmented riparian stands in CZ 2-CZ 8 that do not provide high-value habitat for the species.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 and that are identified in the biological goals and objectives for yellow-breasted chat in Chapter 3 of the BDCP would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat. Using these ratios would indicate that 53 acres of valley/foothill riparian habitat should be restored/created and 53 acres should be protected to compensate for the CM1 losses of yellow-breasted chat habitat. The near-term effects of other conservation actions would remove 468 acres of modeled habitat, and therefore require 468 acres of restoration and 468 acres of protection of valley/foothill riparian using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection).

The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of the valley/foothill riparian natural community in the Plan Area (Table 3-4 in Chapter 3). These conservation actions are associated with CM3 and CM7 and would occur in the same timeframe as the construction and early restoration losses, thereby avoiding adverse effects of habitat loss on yellow-breasted chat. The majority of the riparian restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, Conservation Strategy). Goals and objectives in the Plan for riparian restoration also include the restoration, maintenance and enhancement of structural heterogeneity with adequate vertical and horizontal overlap among vegetation components and over adjacent riverine channels, freshwater emergent wetlands, and grasslands (Objective VFRNC2.1). The yellow-breasted chat has specific structural habitat requirements, so only the early- to mid-successional portions of the restored and protected riparian natural would be expected to provide suitable habitat characteristics for the species. These natural community biological goals and objectives would inform the near-term protection and restoration efforts and represent performance standards for considering the effectiveness of conservation actions for the species.

The acres of protection contained in the near-term Plan goals and the additional detail in the biological objectives for yellow-breasted chat satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1, as well as mitigate the near-term effects of the other conservation measures. The restored riparian habitat could require 5 years to several decades, for
ecological succession to occur and for restored riparian habitat to functionally replace habitat that has been affected. However, because the modeled habitat impacted largely consists of small patches of blackberry, willow, and riparian scrub, BDCP actions would not be expected to have an adverse population-level effect on the species in the near-term time period.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, AMM7 Barge Operations Plan, and AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.

Late Long-Term Timeframe

The habitat model indicates that the study area supports approximately 14,547 acres of modeled nesting and migratory habitat for yellow-breasted chat. Alternative 1B as a whole would result in the permanent loss of and temporary effects on 817 acres of modeled habitat (6% of the modeled habitat in the Plan Area). These losses would occur from the construction of the water conveyance facilities (CM1) and from CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, and CM5 Seasonally Inundated Floodplain Restoration. The locations of these losses would be in fragmented riparian habitat throughout the study area.

The Plan includes conservation commitments through CM7 Riparian Natural Community Restoration and CM3 Natural Communities Protection and Restoration to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill riparian woodland. Of the 5,000 acres of restored riparian natural communities, a minimum of 3,000 acres of valley/foothill riparian would be restored within the seasonally inundated floodplain, and 1,000 acres would be managed as dense early to mid-successional riparian forest (Objectives VFRNC1.1 and VFRNC1.2). The yellow-breasted chat has specific structural habitat requirements, so only the early- to mid-successional portions of the restored and protected riparian natural would be expected to provide suitable habitat characteristics for the species. Fluvial disturbance in restored riparian floodplains would help to maintain early- to mid-successional vegetation. The resulting riparian systems would be subject to natural erosion and deposition, which would provide conditions conducive to the establishment of dense willow stands that are preferred by yellow-breasted chat for nesting. In addition, if monitoring determined that cowbird parasitism was having an effect on the yellow-breasted population in the Plan Area, a cowbird control program would be implemented through CM11 Natural Communities Enhancement and Management. Goals and objectives in the Plan for riparian restoration also include the maintenance and enhancement of structural heterogeneity (Objective VFRNC2.1) which would provide suitable habitat for yellow-breasted chat.

The BDCP’s beneficial effects analysis (BDCP Chapter 5, Section 5.6, Effects on Covered Wildlife and Plant Species) estimates that the restoration and protection actions discussed above could result in the restoration of 2,683 acres and the protection of 594 acres of habitat for the yellow-breasted chat.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention
Alternative 1B
Terrestrial Biological Resources

Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and
Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged
Material, AMM7 Barge Operations Plan, and AMM22 Suisun Song Sparrow, Yellow-Breasted Chat,
Least Bell’s Vireo, Western Yellow-Billed Cuckoo. All of these AMMs include elements that would
avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and
storage sites. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization
Measures.

NEPA Effects: The loss of western yellow-breasted chat habitat and potential direct mortality of this
special-status species would represent an adverse effect in the absence of other conservation
actions. The restored riparian habitat would require 5 years to several decades for ecological
succession to occur and a similar period of time for restored riparian habitat to functionally replace
habitat that has been affected. However, the habitat that would be lost consists of small, fragmented
riparian stands that would not provide high-value habitat for the species. And because the nesting
and migratory habitat that would be lost is small relative to the species range throughout California
and North America, BDCP actions would not be expected to have an adverse population-level effect
on the species. With habitat protection and restoration associated with CM3, CM7, and CM11, guided
by biological goals and objectives and by AMM1 Worker Awareness Training, AMM2 Construction Best
Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion
and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6
Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, AMM7 Barge
Operations Plan, and AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell’s Vireo, Western
Yellow-Billed Cuckoo, which would be in place throughout the construction period, the effects of
habitat loss and potential mortality on yellow-breasted chat under Alternative 1B would not be
adverse.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-
term BDCP conservation strategy has been evaluated to determine whether it would provide
sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the
impact of construction would be less than significant under CEQA. The Plan would remove 521 acres
of modeled habitat for yellow-breasted chat in the study area in the near-term. These effects would
result from the construction of the water conveyance facilities (CM1, 53 acres of modeled nesting
and migratory habitat), and implementing other conservation measures (CM2 Yolo Bypass Fisheries
Enhancement, CM4 Tidal Natural Communities Restoration, and CM5 Seasonally Inundated Floodplain
Restoration—468 acres of modeled nesting and migratory habitat). These habitat losses would
primarily consist of small, fragmented riparian stands in CZ 2-CZ 8 that do not provide high-value
habitat for the species.

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by
CM1 and that are identified in the biological goals and objectives for yellow-breasted chat in Chapter
3 of the BDCP would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian
habitat. Using these ratios would indicate that 53 acres of valley/foothill riparian habitat should be
restored/created and 53 acres should be protected to compensate for the CM1 losses of yellow-
breasted chat habitat. The near-term effects of other conservation actions would remove 468 acres
of modeled habitat, and therefore require 468 acres of restoration and 468 acres of protection of
valley/foot hill riparian using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection).

The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of the valley/foot hill riparian natural community in the Plan Area (Table 3-4 in Chapter 3). These conservation actions are associated with CM3 and CM7 and would occur in the same timeframe as the construction and early restoration losses, thereby avoiding adverse effects of habitat loss on yellow-breasted chat. The majority of the riparian restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foot hill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, Conservation Strategy). Goals and objectives in the Plan for riparian restoration also include the restoration, maintenance and enhancement of structural heterogeneity with adequate vertical and horizontal overlap among vegetation components and over adjacent riverine channels, freshwater emergent wetlands, and grasslands (Objective VFRNC2.1). The yellow-breasted chat has specific structural habitat requirements, so only the early- to mid-successional portions of the restored and protected riparian natural would be expected to provide suitable habitat characteristics for the species. These natural community biological goals and objectives would inform the near-term protection and restoration efforts and represent performance standards for considering the effectiveness of conservation actions for the species.

The acres of protection contained in the near-term Plan goals and the additional detail in the biological objectives for yellow-breasted chat satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1, as well as mitigate the near-term effects of the other conservation measures. The restored riparian habitat could require 5 years to several decades, for ecological succession to occur and for restored riparian habitat to functionally replace habitat that has been affected. However, because the modeled habitat impacted largely consists of small patches of blackberry, willow, and riparian scrub, BDCP actions would not be expected to have a significant population-level impact on the species in the near-term time period.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, AMM7 Barge Operations Plan, and AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell’s Vireo, Western Yellow-Billed Cuckoo. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.

**Late Long-Term Timeframe**

The habitat model indicates that the study area supports approximately 14,547 acres of modeled nesting and migratory habitat for yellow-breasted chat. Alternative 1B as a whole would result in the permanent loss of and temporary effects on 817 acres of modeled habitat (6% of the modeled habitat in the Plan Area). These losses would occur from the construction of the water conveyance facilities (CM1) and from CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, and CM5 Seasonally Inundated Floodplain Restoration. The locations of these losses would be in fragmented riparian habitat throughout the study area.
The Plan includes conservation commitments through *CM7 Riparian Natural Community Restoration* and *CM3 Natural Communities Protection and Restoration* to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill riparian woodland. Of the 5,000 acres of restored riparian natural communities, a minimum of 3,000 acres of valley/foothill riparian would be restored within the seasonally inundated floodplain, and 1,000 acres would be managed as dense early to mid-successional riparian forest (Objectives VFRNC1.1 and VFRNC1.2). The yellow-breasted chat has specific structural habitat requirements, so only the early- to mid-successional portions of the restored and protected riparian natural would be expected to provide suitable habitat characteristics for the species. Fluvial disturbance in restored riparian floodplains would help to maintain early- to mid-successional vegetation. The resulting riparian systems would be subject to natural erosion and deposition, which would provide conditions conducive to the establishment of dense willow stands that are preferred by yellow-breasted chat for nesting. In addition, if monitoring determined that cowbird parasitism was having an effect on the yellow-breasted population in the Plan Area, a cowbird control program would be implemented through *CM11 Natural Communities Enhancement and Management*. Goals and objectives in the Plan for riparian restoration also include the maintenance and enhancement of structural heterogeneity (Objective VFRNC2.1) which would provide suitable habitat for yellow-breasted chat.

The BDCP’s beneficial effects analysis (BDCP Chapter 5, Section 5.6, *Effects on Covered Wildlife and Plant Species*) estimates that the restoration and protection actions discussed above could result in the restoration of 2,683 acres and the protection of 594 acres of habitat for the yellow-breasted chat.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training*, *AMM2 Construction Best Management Practices and Monitoring*, *AMM3 Stormwater Pollution Prevention Plan*, *AMM4 Erosion and Sediment Control Plan*, *AMM5 Spill Prevention, Containment, and Countermeasure Plan*, *AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, *AMM7 Barge Operations Plan*, and *AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell’s Vireo, Western Yellow-Billed Cuckoo*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*.

Considering Alternative 1B’s protection and restoration provisions, which would provide acreages of new or enhanced habitat in amounts suitable to compensate for habitats lost to construction and restoration activities, and with implementation of AMM1–AMM7 and AMM22 *Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell’s Vireo, Western Yellow-Billed Cuckoo*, the loss of habitat or direct mortality through implementation of Alternative 1B would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on western yellow-breasted chat.

**Impact BIO-105: Fragmentation of Yellow-Breasted Chat Habitat as a Result of Constructing the Water Conveyance Facilities**

Grading, filling, contouring, and other initial ground-disturbing activities for water conveyance facilities construction may temporarily fragment modeled yellow-breasted chat habitat. This could temporarily reduce the extent of and functions supported by the affected habitat. Because of the current infrequent occurrence and small numbers of yellow-breasted chat in the Plan Area, and
because CM5 Seasonally Inundated Floodplain Restoration would restore and protect contiguous high-value riparian habitat in CZ 7, any such habitat fragmentation is expected to have no or minimal effect on the species.

**NEPA Effects:** Temporary fragmentation of habitat would not result in an adverse effect on yellow-breasted chat. The habitat functions for the species would be significantly improved through the implementation of CM5, which would restore and protect large contiguous patches of riparian habitat.

**CEQA Conclusion:** Temporary fragmentation of habitat would have a less-than-significant impact on yellow-breasted chat. The habitat functions for the species would be significantly improved through the implementation of CM5, which would restore and protect large contiguous patches of riparian habitat.

**Impact BIO-106: Effects on Yellow-Breasted Chat Associated with Electrical Transmission Facilities**

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of western yellow-billed cuckoo. Yellow-breasted chats are migratory and usually arrive at California breeding grounds in April from their wintering grounds in Mexico and Guatemala. Departure for wintering grounds occurs from August to September. These are periods of relative high visibility when the risk of powerline collisions will be low. The species’ small, relatively maneuverable body; its foraging behavior; and its presence in the Plan Area during the summer contribute to a low risk of collision with the proposed transmission lines (BDCP Attachment 5J.C, Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines). New transmission lines would therefore not be expected to have an adverse effect on yellow-breasted chat.

**NEPA Effects:** The construction and presence of new transmission lines would not result in an adverse effect on yellow-breasted chat because the risk of bird strike is considered to be minimal based on the species’ small, relatively maneuverable body; its foraging behavior; and its presence in the study area during the summer when visibility is high.

**CEQA Conclusion:** The construction and presence of new transmission lines would have a less-than-significant impact on yellow-breasted chat because the risk of bird-strike is considered to be minimal based on the species’ small, relatively maneuverable body; its foraging behavior; and its presence in the study area during the summer when visibility is high.

**Impact BIO-107: Indirect Effects of Plan Implementation on Yellow-Breasted Chat**

Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect yellow-breasted chat use of modeled habitat adjacent to proposed construction areas. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane, Table 4), although there are no available data to determine the extent to which these noise levels could affect yellow-breasted chat. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations outside the project footprint but within 1,300 feet of the construction edge. If yellow-breasted chat were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and
reduce the functions of suitable nesting habitat for these species. These potential effects would be
minimized with incorporation of AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's
Vireo, Western Yellow-Billed Cuckoo into the BDCP, which would ensure 250-foot no-disturbance
buffers were established around active nests. The use of mechanical equipment during water
conveyance facilities construction could cause the accidental release of petroleum or other
contaminants that could affect yellow-breasted chat in the surrounding habitat. The inadvertent
discharge of sediment or excessive dust adjacent to yellow-breasted chat habitat could also affect
the species. AMM1–AMM7, including AMM2 Construction BMPs and Monitoring, in addition to
AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western Yellow-Billed Cuckoo,
would minimize the likelihood of such spills from occurring and ensure that measures were in place
to prevent runoff from the construction area and any adverse effects of dust on active nests. If
present, yellow-breasted chat individuals could be temporarily affected by noise and visual
disturbances adjacent to water conveyance construction sites, AMM22 would minimize this effect on
the species.

NEPA Effects: The potential for noise and visual disturbance, hazardous spills, increased dust and
sedimentation, and the potential impacts of operations and maintenance of the water conveyance
facilities would not result in an adverse effect on yellow-breasted chat with the incorporation of
AMM1–AMM7 and AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's Vireo, Western
Yellow-Billed Cuckoo into the BDCP.

CEQA Conclusion: The potential for noise and visual disturbance, hazardous spills, increased dust
and sedimentation, and the potential impacts of operations and maintenance of the water
conveyance facilities would have a less-than-significant impact on yellow-breasted chat with the
incorporation of AMM1–AMM7 and AMM22 Suisun Song Sparrow, Yellow-Breasted Chat, Least Bell's
Vireo, Western Yellow-Billed Cuckoo into the BDCP.

Impact BIO-108: Periodic Effects of Inundation of Yellow-Breasted Chat Habitat as a Result of
Implementation of Conservation Components

Flooding of the Yolo Bypass from Fremont Weir operations (CM2) would increase the frequency and
duration of inundation of approximately 48–88 acres of modeled yellow-breasted chat nesting and
migratory habitat. No adverse effects of increased inundation frequency on yellow-breasted chat or
its habitat are expected because the chat breeding period is outside the period the weir would be
operated. Moreover, riparian vegetation supporting habitat has persisted under the existing Yolo
Bypass flooding regime, and changes to frequency and inundation would be within the tolerance of
these vegetation types.

Based on hypothetical floodplain restoration, CM5 could result in periodic inundation of up to 148
acres of modeled yellow-breasted chat habitat. Inundation of restored floodplains is not expected to
affect yellow-breasted chat or its habitat because the chat breeding period is outside the period the
floodplains would likely be inundated. In addition, providing for periodic inundation of floodplains
is expected to restore a more natural flood regime in support of riparian vegetation types that
provide nesting and migratory habitat for yellow-breasted chat. The overall effect of seasonal
inundation in existing riparian natural communities is likely to be beneficial because, historically,
flooding was the main natural disturbance regulating ecological processes in riparian areas, and
flooding promotes the germination and establishment of many native riparian plants.
**NEPA Effects:** Increases in the frequency and duration of Yolo Bypass flooding and CM5 floodplain restoration would be expected to create more natural flood regimes that would support riparian habitat, which would not result in an adverse effect on yellow breasted chat.

**CEQA Conclusion:** By creating more natural flood regimes that would support riparian habitat, increases in the frequency and duration of Yolo Bypass flooding and CM5 floodplain restoration would have a beneficial impact on yellow breasted chat.

### Cooper’s Hawk and Osprey

This section describes the effects of Alternative 1B, including water conveyance facilities construction and implementation of other conservation components, on Cooper’s hawk and osprey. Although osprey often nest on manmade structures such as telephone poles, and Cooper’s hawk will nest in more developed landscapes, modeled nesting habitat for these species is restricted to valley/foothill riparian forest.

Construction and restoration associated with Alternative 1B conservation measures would result in both temporary and permanent losses of Cooper’s hawk and osprey modeled habitat as indicated in Table 12-1B-43. The majority of the losses would take place over an extended period of time as tidal marsh is restored in the study area. Although restoration for the loss of nesting habitat would be initiated in the same timeframe as the losses, it could take one or more decades for restored habitats to replace the functions of habitat lost. This time lag between impacts and restoration of habitat function would be minimized by specific requirements of **AMM18 Swainson’s Hawk and White-Tailed Kite**, including the planting of mature trees in the near-term time period. Full implementation of Alternative 1B would include the following conservation actions over the term of the BDCP which would also benefit Cooper’s hawk and osprey (BDCP Chapter 3, Section 3.3, **Biological Goals and Objectives**).

- Restore or create at least 5,000 acres of valley/foothill riparian natural community, with at least 3,000 acres occurring on restored seasonally inundated floodplain (Objective VFRNC1.1, associated with CM7)
- Protect at least 750 acres of existing valley/foothill riparian natural community in CZ 7 by year 10 (Objective VFRNC1.2, associated with CM3).
- Plant and maintain native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SH2.1, associated with CM11).
- Maintain and protect the small patches of important wildlife habitats associated with cultivated lands within the reserve system including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Objective CLNC1.3, associated with CM3).

As explained below, with the acres of restoration or protection included in the Plan, in addition to management activities to enhance natural communities for species and implementation of AMM1-AMM7, **AMM18 Swainson's Hawk and White-Tailed Kite**, and Mitigation Measure BIO-75, impacts on Cooper’s hawk and osprey would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

a See Appendix 12E for detailed breakdown of conservation measure effects over the BDCP’s near-
term and late long-term timeframes.
b See discussion below for a description of applicable CMs.
c LLT acreages are a summation of effects that would occur in the near-term, early long-term and late
long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected
over the 50-year life of the BDCP and do not reflect habitat increases that would result from
restoration, creation and protection activities.
d Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a
range based on different flow regimes at the proposed notch in Fremont Weir.

NT = near-term
LLT = late long-term

Impact BIO-109: Loss or Conversion of Habitat for and Direct Mortality of Cooper’s Hawk and
Osprey

Alternative 1B conservation measures would result in the combined permanent and temporary loss
of up to 707 acres of modeled nesting habitat (547 acres of permanent loss, 160 acres of temporary
loss) habitat for Cooper’s hawk and osprey (Table 12-1B-43). Conservation measures that would
result in these losses are **CM1 Water Facilities and Operation** (which would involve construction of
conveyance facilities and transmission lines and establishment and use of borrow and spoil areas),
**CM2 Yolo Bypass Fisheries Enhancement**, **CM4 Tidal Natural Communities Restoration**, and **CM5
Seasonally Inundated Floodplain Restoration**. Habitat enhancement and management activities
(CM11), which would include ground disturbance or removal of nonnative vegetation, could result
in local adverse habitat effects. In addition, maintenance activities associated with the long-term
operation of the water conveyance facilities and other BDCP physical facilities could affect Cooper’s
hawk and osprey modeled habitat. Each of these individual activities is described below. A summary
statement of the combined impacts and NEPA and CEQA conclusions follows the individual
conservation measure discussions.

- **CM1 Water Facilities and Operation**: Construction of Alternative 1B water conveyance facilities
would result in the combined permanent and temporary loss of up to 79 acres of modeled
Cooper’s hawk and osprey habitat (Table 12-1B-43). Of the 79 acres of modeled habitat that
would be removed for the construction of the conveyance facilities, 40 acres would be a
permanent loss and 39 acres would be a temporary loss of habitat. The habitat would be
removed at multiple locations from the north Delta to the east Delta and in the vicinity of Clifton
Court Forebay. Almost all of the losses would occur on the borders of waterways. In the north
Delta, most of the permanent loss would occur where Intakes 1–5 encroach on the Sacramento
River’s east bank between Freeport and Courtland. The riparian areas here are very small patches, some dominated by valley oak and others by nonnative trees and scrub vegetation. Other small patches or narrow bands of riparian vegetation dominated by valley oak, willow, cottonwood or mixed brambles would be permanently removed by canal construction adjacent to Intake 1, between Intakes 2 and 4, and just south of Lambert Road. In the east Delta, small permanent losses would occur from canal construction just south of Twin Cities Road and just north of Walnut Grove Road. The temporary riparian losses would occur at the intake sites along the Sacramento River and at temporary siphon work areas where the canal would cross Beaver Slough, Hog Slough, Sycamore Slough, White Slough, Disappointment Slough, Railroad Canal, and Middle River just south of Victoria Canal. There are no occurrences of Cooper’s hawk or osprey that overlap with the construction footprint for CM1. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds would be available to address potential effects on Cooper’s hawk and osprey if either species were to nest in or adjacent to the construction footprint. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 1B construction locations.

- **CM2 Yolo Bypass Fisheries Enhancement:** Construction of the Yolo bypass fisheries enhancement would result in the combined permanent and temporary loss of up to 170 acres of Cooper’s hawk and osprey nesting habitat (82 acres of permanent loss, 88 acres of temporary loss) in the Yolo Bypass in CZ 2. Activities through CM2 could involve excavation and grading in valley/foothill riparian areas to improve passage of fish through the bypasses. Most of the riparian losses would occur at the north end of Yolo Bypass where major fish passage improvements are planned. Excavation to improve water movement in the Toe Drain and in the Sacramento Weir would also remove potential Cooper’s hawk and osprey habitat. The loss is expected to occur during the first 10 years of Alternative 1B implementation.

- **CM4 Tidal Natural Communities Restoration:** Tidal habitat restoration could permanently remove up to 383 acres of potential Cooper’s hawk and osprey nesting habitat. Trees would not be actively removed but tree mortality would be expected over time as areas became tidally inundated.

- **CM5 Seasonally Inundated Floodplain Restoration:** Construction of setback levees to restore seasonally inundated floodplain and riparian restoration actions would remove approximately 75 acres of Cooper’s hawk and osprey nesting habitat (42 acres of permanent loss, 33 acres of temporary loss). These losses would be expected after the first 10 years of Alternative 1B implementation along the San Joaquin River and other major waterways in CZ 7.

- **CM11 Natural Communities Enhancement and Management:** Habitat management- and enhancement-related activities could disturb Cooper’s hawk and osprey nests if they were present near work sites. A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in BDCP-protected habitats may result in localized ground disturbances that could temporarily remove small amounts of Cooper’s hawk and osprey habitat and reduce the functions of habitat until restoration is complete. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor effects on available Cooper’s hawk and osprey habitat and are expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below.
Permanent and temporary habitat losses from the above conservation measures would primarily consist of fragmented riparian stands. Temporarily affected areas would be restored as riparian habitat within 1 year following completion of construction activities. Although the effects are considered temporary, the restored riparian habitat would require 1 to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by Cooper’s hawk or osprey. AMM18 Swainson’s Hawk and White-Tailed Kite contains actions described below to reduce the effect of temporal loss of nesting habitat, including the transplanting of mature trees.

- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect Cooper’s hawk or osprey use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7 and conservation actions as described below.

- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged Cooper’s hawk or osprey if they were present in the Plan Area, because they would be expected to avoid contact with construction and other equipment. If Cooper’s hawk or osprey were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could affect nests or lead to their abandonment, potentially resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would be available to address these adverse effects on Cooper’s hawk and osprey.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effect of construction would not be adverse under NEPA. The Plan would remove 449 acres (338 acres of permanent loss, 111 acres of temporary loss) of Cooper’s hawk and osprey nesting habitat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 49 acres), and implementing other conservation measures (CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, and CM5 Seasonally Inundated Floodplain Restoration—400 acres of habitat).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat. Using these ratios would indicate that 49 acres of nesting habitat should be restored/created and 49 acres should be protected to compensate for the CM1 losses of modeled Cooper’s hawk and osprey habitat. In addition, The near-term effects of other conservation actions would remove 400 acres of modeled breeding habitat, and therefore require 400 acres of restoration and 400 acres of protection of modeled Cooper’s hawk and osprey using the same typical NEPA and CEQA ratios.

The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of valley/foothill riparian natural community (Table 3-4 in Chapter 3). These conservation actions are
associated with CM3, and CM7 and would occur in the same timeframe as the construction and early
restoration losses. The majority of riparian protection and restoration acres would occur in CZ.7 as
part of a reserve system with extensive wide bands or large patches of valley/foothill riparian
natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, Conservation Strategy).
Riparian restoration would expand the patches of existing riparian forest in order to support nesting
habitat for riparian species. The Plan’s objectives would also benefit Cooper’s hawk and osprey by
protecting small but essential habitats that occur within cultivated lands, such as tree rows along
field borders or roads, and small clusters of trees in farmyards or rural residences(Objective
CLNC1.3). In addition, the distribution and abundance of potential nest trees would be increased by
planting and maintaining native trees along roadsides and field borders within protected cultivated
lands at a rate of one tree per 10 acres (Objective SWHA2.1).

The 750 acres of protection and 800 acres of restoration contained in the near-term Plan goals
satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1 and
other near-term impacts on Cooper’s hawk and osprey nesting habitat. The 800 acres of restored
riparian habitat would be initiated in the near-term to offset the loss of modeled nesting habitat, but
would require one to several decades to functionally replace habitat that has been affected and for
trees to attain sufficient size and structure suitable for nesting by these species. This time lag
between the removal and restoration of nesting habitat could have a substantial impact on nesting
raptors in the near-term time period. Nesting habitat is limited throughout much of the study area,
consisting mainly of intermittent riparian, isolated trees, small groves, tree rows along field borders,
roadside trees, and ornamental trees near rural residences. The removal of nest trees or nesting
habitat could further reduce this limited resource and reduce or restrict the number of active nests
within the study area until restored riparian habitat is sufficiently developed.

AMM18 Swainson’s Hawk and White-Tailed Kite would implement a program to plant large mature
trees, including transplanting trees scheduled for removal. These would be supplemented with
additional saplings and would be expected to reduce the temporal effects of loss of nesting habitat.
The plantings would occur prior to or concurrent with (in the case of transplanting) the loss of trees.
In addition, at least five trees (5-gallon container size) would be planted within the BDCP reserve
system for every tree 20 feet or taller anticipated to be removed by construction during the near-
term period. A variety of native tree species would be planted to provide trees with differing growth
rates, maturation, and life span. Trees would be planted within the BDCP reserve system in clumps
of at least three trees each at appropriate sites within or adjacent to conserved cultivated lands, or
they could be incorporated as a component of the riparian restoration (CM5, CM7). Replacement
trees that were incorporated into the riparian restoration would not be clustered in a single region
of the study area, but would be distributed throughout the conserved lands.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2
Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention
Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and
Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged
Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or
minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are
described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures. Cooper’s hawk and
osprey are not species that are covered under the BDCP. For the BDCP to avoid having an adverse
effect on individuals, preconstruction surveys for noncovered avian species would be required to
ensure that active nests are detected and avoided. Mitigation Measure BIO-75, Conduct
Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would be available to address this adverse effect.

Late Long-Term Timeframe

The study area supports approximately 14,069 acres of modeled nesting habitat for Cooper's hawk and osprey. Alternative 1B as a whole would result in the permanent loss of and temporary effects on 677 acres of potential nesting habitat (5% of the potential nesting habitat in the study area).

The Plan includes conservation commitments through CM3 Natural Communities Protection and Restoration, CM5 Seasonally Inundated Floodplain Restoration, and CM7 Riparian Natural Community Restoration to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill riparian natural community (Table 3-4 in Chapter 3). The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, Conservation Strategy). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for riparian species. The Plan's objectives would also benefit Cooper's hawk and osprey by protecting small but essential habitats that occur within cultivated lands, such as tree rows along field borders or roads, and small clusters of trees in farmyards or rural residences (Objective CLNC1.3). In addition, the distribution and abundance of potential nest trees would be increased by planting and maintaining native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SWHA2.1).

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures. Cooper's hawk and osprey are not species that are covered under the BDCP. For the BDCP to avoid having an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that active nests are detected and avoided. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would be available to address this adverse effect.

NEPA Effects: The loss of Cooper’s hawk and osprey habitat and potential for direct mortality of these special-status species under Alternative 1B would represent an adverse effect in the absence of other conservation actions. However, with habitat protection and restoration associated with CM3, CM5, CM7, guided by biological goals and objectives and by AMM1–AMM7 and AMM18 Swainson’s Hawk and White-Tailed Kite, which would be in place throughout the construction period, the effects of habitat loss on Cooper’s hawk and osprey under Alternative 1B would not be adverse. Cooper’s hawk and osprey are not covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75 would be available to address this adverse effect.
**CEQA Conclusion:**

**Near-Term Timeframe**

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effect of construction would not be adverse under NEPA. The Plan would remove 449 acres (338 acres of permanent loss, 111 acres of temporary loss) of Cooper’s hawk and osprey nesting habitat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 49 acres), and implementing other conservation measures (CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, and CM5 Seasonally Inundated Floodplain Restoration—400 acres of habitat).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat. Using these ratios would indicate that 49 acres of nesting habitat should be restored/created and 49 acres should be protected to mitigate the CM1 losses of modeled Cooper’s hawk and osprey habitat. In addition, the near-term effects of other conservation actions would remove 400 acres of modeled breeding habitat, and therefore require 400 acres of restoration and 400 acres of protection of modeled Cooper’s hawk and osprey using the same typical NEPA and CEQA ratios. The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of valley/foothill riparian natural community (Table 3-4 in Chapter 3). These conservation actions are associated with CM3, and CM7 and would occur in the same timeframe as the construction and early restoration losses. The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, Conservation Strategy).

Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for riparian species. The Plan’s objectives would also benefit Cooper’s hawk and osprey by protecting small but essential habitats that occur within cultivated lands, such as tree rows along field borders or roads, and small clusters of trees in farmyards or rural residences(Objective CLNC1.3). In addition, the distribution and abundance of potential nest trees would be increased by planting and maintaining native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SWHA2.1).

The 750 acres of protection and 800 acres of restoration contained in the near-term Plan goals satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1 and other near-term impacts on Cooper’s hawk and osprey nesting habitat. The 800 acres of restored riparian habitat would be initiated in the near-term to offset the loss of modeled nesting habitat, but would require one to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for nesting by these species. This time lag between the removal and restoration of nesting habitat could have a substantial impact on nesting raptors in the near-term time period. Nesting habitat is limited throughout much of the study area, consisting mainly of intermittent riparian, isolated trees, small groves, tree rows along field borders, roadside trees, and ornamental trees near rural residences. The removal of nest trees or nesting habitat would further reduce this limited resource and could reduce or restrict the number of active nests within the study area until restored riparian habitat is sufficiently developed.
AMM18 Swainson’s hawk and White-Tailed Kite would implement a program to plant large mature
trees, including transplanting trees scheduled for removal. These would be supplemented with
additional saplings and would be expected to reduce the temporal effects of loss of nesting habitat.
The plantings would occur prior to or concurrent with (in the case of transplanting) the loss of trees.
In addition, at least five trees (5-gallon container size) would be planted within the BDCP reserve
system for every tree 20 feet or taller anticipated to be removed by construction during the near-
term period. A variety of native tree species would be planted to provide trees with differing growth
rates, maturation, and life span. Trees would be planted within the BDCP reserve system in clumps
of at least three trees each at appropriate sites within or adjacent to conserved cultivated lands, or
they could be incorporated as a component of the riparian restoration (CM5, CM7). Replacement
trees that were incorporated into the riparian restoration would not be clustered in a single region
of the study area, but would be distributed throughout the conserved lands.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2
Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention
Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and
Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged
Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or
minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are
described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures. Cooper’s hawk and
osprey are not species that are covered under the BDCP. For the BDCP to avoid having a significant
impact on individuals, preconstruction surveys for noncovered avian species would be required to
ensure that active nests are detected and avoided. Implementation of Mitigation Measure BIO-75
would reduce the potential impact on nesting Cooper’s hawk and osprey to a less-than-significant
level.

Late Long-Term Timeframe

The study area supports approximately 14,069 acres of modeled nesting habitat for Cooper’s hawk
and osprey. Alternative 1B as a whole would result in the permanent loss of and temporary effects
on 677 acres of potential nesting habitat (5% of the potential nesting habitat in the study area).

The Plan includes conservation commitments through CM3 Natural Communities Protection and
Restoration, CM5 Seasonally Inundated Floodplain Restoration, and CM7 Riparian Natural Community
Restoration to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill
riparian natural community (Table 3-4 in Chapter 3). The majority of riparian protection and
restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large
patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP
Chapter 3, Conservation Strategy). Riparian restoration would expand the patches of existing
riparian forest in order to support nesting habitat for riparian species. The Plan’s objectives would
also benefit Cooper’s hawk and osprey by protecting small but essential habitats that occur within
cultivated lands, such as tree rows along field borders or roads, and small clusters of trees in
farmyards or rural residences(Objective CLNC1.3). In addition, the distribution and abundance of
potential nest trees would be increased by planting and maintaining native trees along roadsides
and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective
SWHA2.1).

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2
Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention
Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures. Cooper’s hawk and osprey are not species that are covered under the BDCP. For the BDCP to have a less-than-significant impact on individuals, preconstruction surveys for noncovered avian species would be required to ensure that active nests are detected and avoided. Implementation of Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would reduce this impact to a less-than-significant level.

Considering these protection and restoration provisions, which would provide acreages of new or enhanced habitat in amounts greater than necessary to compensate for the time lag of restoring riparian habitats lost to construction and restoration activities, and with implementation of AMM1–AMM7, AMM18 Swainson’s Hawk and White-Tailed Kite, and Mitigation Measure BIO-75, the loss of habitat or direct mortality through implementation of Alternative 1B would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of either species. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on Cooper’s hawk and osprey.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-110: Effects on Cooper’s Hawk and Osprey Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of Cooper’s hawk and osprey. The existing network of transmission lines in the Plan Area currently poses the same small risk for Cooper’s hawk and osprey, and any incremental risk associated with the new power line corridors would also be expected to be low. AMM20 Greater Sandhill Crane, which would install flight-diverters on new and selected existing transmission lines would further reduce any adverse effects.

NEPA Effects: New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of Cooper’s hawk and osprey. With the implementation of AMM20 Greater Sandhill Crane, which would install flight-diverters on new and selected existing transmission lines, there would not be an adverse effect on Cooper’s hawk and osprey.

CEQA Conclusion: New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of Cooper’s hawk and osprey. AMM20 Greater Sandhill Crane, which would install flight-diverters on new and selected existing transmission lines, would minimize this risk would reduce the impact of new transmission lines on Cooper’s hawk and osprey to a less-than-significant level.

Impact BIO-111: Indirect Effects of Plan Implementation on Cooper’s Hawk and Osprey

Indirect construction- and operation-related effects: Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction.
Terrestrial Biological Resources

activities (BCDP Appendix 5J, Attachment 5J.D, Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane, Table 4), although there are no available data to determine the extent to which these noise levels could affect Cooper’s hawk or osprey. If Cooper’s hawk or osprey were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would avoid the potential for adverse effects of construction-related activities on survival and productivity of nesting Cooper’s hawk and osprey. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect Cooper’s hawk and osprey in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to suitable habitat could also have an adverse effect on these species. AMM1–AMM7, including AMM2 Construction Best Management Practices and Monitoring, would minimize the likelihood of such spills and ensure that measures are in place to prevent runoff from the construction area and negative effects of dust on active nests.

**Methylmercury Exposure:** Covered activities have the potential to exacerbate bioaccumulation of mercury in avian species, including Cooper’s hawk and osprey. Future operational impacts under CM1 were analyzed using a DSM-2 based model to assess potential effects on mercury concentration and bioavailability resulting from proposed flows. Subsequently, a regression model was used to estimate fish-tissue concentrations under these future operational conditions (evaluated starting operations or ESO). Results indicated that changes in total mercury levels in water and fish tissues due to ESO were insignificant (see BDCP Appendix 5D, Tables 5D.4-3, 5D.4-4, and 5D.4-5).

Marsh (tidal and nontidal) and floodplain restoration have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury (see BDCP Chapter 3, Conservation Strategy, for details of restoration). Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community and floodplain restoration could indirectly affect cooper’s hawk and osprey, via uptake in lower tropic levels (as described in the BDCP, Appendix 5.D, Contaminants).

In addition, the potential mobilization or creation of methylmercury within the Plan Area varies with site-specific conditions and would need to be assessed at the project level. CM12 Methylmercury Management contains provisions for project-specific Mercury Management Plans. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would be available to address the uncertainty of methylmercury levels in restored tidal marsh and potential impacts on cooper’s hawk and osprey.

**NEPA Effects:** Noise and visual disturbances from the construction of water conveyance facilities could reduce Cooper’s hawk and osprey use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect Cooper’s hawk and osprey use of the surrounding habitat. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would be available to address adverse effects on nesting individuals in addition to AMM1–AMM7. The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of Cooper’s...
hawk or osprey to methylmercury, through the ingestion of fish or small mammals in tidally
restored areas. However, it is currently unknown what concentrations of methylmercury are
harmful to these species and the potential for increased exposure varies substantially within the
study area. Site-specific restoration plans that address the creation and mobilization of mercury, as
well as monitoring and adaptive management as described in CM12 would better inform potential
impacts and address the uncertainty of methylmercury levels in restored tidal marsh in the study
area on cooper's hawk and osprey. The site-specific planning phase of marsh restoration would be
the appropriate place to assess the potential for risk of methylmercury exposure for Cooper's hawk
and osprey, once site specific sampling and other information could be developed.

**CEQA Conclusion:** Noise and visual disturbances from the construction of water conveyance
facilities could reduce Cooper's hawk and osprey use of modeled habitat adjacent to work areas.
Moreover, operation and maintenance of the water conveyance facilities, including the transmission
facilities, could result in ongoing but periodic postconstruction disturbances that could affect
Cooper's hawk and osprey use of the surrounding habitat. Noise, the potential for hazardous spills,
increased dust and sedimentation, and operations and maintenance of the water conveyance
facilities under Alternative 1B would have a less-than-significant impact on Cooper's hawk and
osprey with the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird
Surveys and Avoid Disturbance of Nesting Birds*, and AMM1–AMM7. The implementation of tidal
natural communities restoration or floodplain restoration could result in increased exposure of
Cooper's hawk or osprey to methylmercury through the ingestion of fish or small mammals in
restored tidal areas. However, it is currently unknown what concentrations of methylmercury are
harmful to these species. Site-specific restoration plans that address the creation and mobilization of
mercury, as well as monitoring and adaptive management as described in CM12, would address the
uncertainty of methylmercury levels in restored tidal marsh in the study area and better inform
potential impacts on Cooper's hawk and osprey.

**Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid
Disturbance of Nesting Birds**

See Mitigation Measure BIO-75 under Impact BIO-75.

**Impact BIO-112: Periodic Effects of Inundation of Cooper’s Hawk and Osprey Nesting Habitat
as a Result of Implementation of Conservation Components**

Flooding of the Yolo Bypass from Fremont Weir operations (CM2) would increase the frequency and
duration of inundation of approximately 48-82 acres of modeled Cooper's hawk and osprey
breeding habitat. However, increased periodic flooding is not expected to cause any adverse effect on
breeding habitat because trees in which nest sites are situated already withstand floods, the
increase in inundation frequency and duration is expected to remain within the range of tolerance of
riparian trees, and nest sites are located above floodwaters.

Based on hypothetical floodplain restoration, CM5 implementation could result in periodic
inundation of up to 230 acres of breeding habitat for Cooper's hawk and osprey. The overall effect of
seasonal inundation in existing riparian natural communities is likely to be beneficial for these
species, because, historically, flooding was the main natural disturbance regulating ecological
processes in riparian areas, and flooding promotes the germination and establishment of many
native riparian plants.
**NEPA Effects:** Increased periodic flooding would not be expected to cause any adverse effect on nest sites because trees in which nest sites are situated already withstand floods, the increase in inundation frequency and duration is expected to remain within the range of tolerance of riparian trees, and nest sites are located above floodwaters. Therefore, increased duration of periodic inundation resulting from CM2 and CM5 would not have an adverse effect on Cooper’s hawk and osprey.

**CEQA Conclusion:** Increased periodic flooding would not be expected to cause any adverse effect on nest sites because trees in which nest sites are situated already withstand floods, the increase in inundation frequency and duration is expected to remain within the range of tolerance of riparian trees, and nest sites are located above floodwaters. Therefore, increased duration of periodic inundation resulting from CM2 and CM5 would have a less-than-significant impact on Cooper’s hawk and osprey.

**Golden Eagle and Ferruginous Hawk**

This section describes the effects of Alternative 1B, including water conveyance facilities construction and implementation of other conservation components, on golden eagle and ferruginous hawk. Modeled foraging habitat for these species consists of grassland, alkali seasonal wetland, vernal pool complex, alfalfa, grain and hay, pasture, and idle cropland throughout the study area.

Construction and restoration associated with Alternative 1B conservation measures would result in both temporary and permanent losses of golden eagle and ferruginous hawk modeled foraging habitat as indicated in Table 12-1B-44. Full implementation of Alternative 1B would include the following conservation actions over the term of the BDCP that would also benefit golden eagles or ferruginous hawk (BDCP Chapter 3, Section 3.3, *Biological Goals and Objectives*).

- Protect at least 8,000 acres of grassland with at least 2,000 acres protected in CZ 1, at least 1,000 acres protected in CZ 8, at last 2,000 acres protected in CZ 11, and the remainder distributed among CZs 1, 2, 4, 5, 7, 8, and 11 (Objective GNC1.1, associated with CM3).

- Restore at least 2,000 acres of grasslands (Objective GNC1.2, associated with CM8).

- Protect at least 150 acres of alkali seasonal wetland and at least 600 acres of existing vernal pool complex in CZs 1, 8, and/or 11 (Objectives ASWNC1.1 and VPNC1.1, associated with CM3).

- Increase prey availability and accessibility for grassland-foraging species (Objectives ASWNC2.4, VPNC2.5, and GNC2.4, associated with CM11).

- Protect at least 48,625 acres of cultivated lands that provide suitable habitat for covered and other native wildlife species (Objective CLNC1.1, associated with CM3).

- Within the at least 48,625 acres of protected cultivated lands, protect at least 42,275 acres of cultivated lands as Swainson’s hawk foraging habitat with at least 50% in very high-value habitat in CZs 2, 3, 4, 5, 7, 8, 9, and 11 (Objective SH1.2, associated with CM3).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities to enhance natural communities for species and implementation of AMM1–AMM7, impacts on golden eagle and ferruginous hawk would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.
Table 12-1B-44. Changes in Golden Eagle and Ferruginous Hawk Habitat Associated with Alternative 1B (acres)a

a See Appendix 12E for detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
b See discussion below for a description of applicable CMs.
c LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
d Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

Impact BIO-113: Loss or Conversion of Habitat for and Direct Mortality of Golden Eagle and Ferruginous Hawk

Alternative 1B conservation measures would result in the combined permanent and temporary loss of up to 34,581 acres of modeled foraging habitat for golden eagle and ferruginous hawk (29,160 acres of permanent loss and 5,421 acres of temporary loss; Table 12-1B-44). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass fisheries improvements (CM2), tidal habitat restoration (CM4), floodplain restoration (CM5), riparian restoration (CM7), grassland restoration (CM8), vernal pool and wetland restoration (CM9), nontidal marsh restoration (CM10), and construction of conservation hatcheries (CM18). The majority of habitat loss (20,880 acres) would result from CM4. Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, and the construction of recreational trails, signs, and facilities, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate golden eagle foraging habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follows the individual conservation measure discussions.

- **CM1 Water Facilities and Operation:** Construction of Alternative 1B conveyance facilities would result in the combined permanent and temporary loss of up to 7,490 acres of modeled golden eagle and ferruginous hawk foraging habitat (2,962 acres of permanent loss, 4,528 acres of temporary loss) from CZ 4, CZ 5, CZ 6, CZ 7, and CZ 8. The permanent and temporary losses would occur at various locations along the new canal route from the transmission line footprint, the construction of the canal and the associated borrow and spoil sites and at the intake sites.
along the Sacramento River. Permanent and temporary losses of foraging habitat would also
coccur at the new forebay site just south of Clifton Court Forebay and associated borrow and
spoil sites. The CM1 construction footprint does not overlap with any occurrences of golden
eagle or ferruginous hawk. However, some of the grassland habitat lost in CZ 8 is composed of
larger stands of ruderal and herbaceous vegetation and California annual grassland, which
provides high-value foraging habitat for these species. There are no Refer to the Terrestrial
Biology Map Book for a detailed view of Alternative 1B construction locations.

- **CM2 Yolo Bypass Fisheries Enhancement:** Construction of the Yolo bypass fisheries enhancement
would result in the combined permanent and temporary loss of up to 1,274 acres of modeled
golden eagle and ferruginous hawk foraging habitat (898 acres of permanent loss, 376 acres of
temporary loss) in the Yolo Bypass in CZ 2. Impacted habitat would consist primarily of
grassland and pasture. Most of the grassland losses would occur at the north end of the bypass
below Fremont Weir, along the Toe Drain/Tule Canal, and along the west side channels.
Realignment of Putah Creek could also involve excavation and grading in alkali seasonal wetland
complex habitat as a new channel is constructed. The loss is expected to occur during the first 10
years of Alternative 1B implementation.

- **CM4 Tidal Natural Communities Restoration:** Tidal habitat restoration (CM4) site preparation
and inundation would permanently remove an estimated 20,880 acres of modeled golden eagle
and ferruginous hawk habitat. The majority of the acres lost would consist of cultivated lands in
CZs 1, 2, 4, 5, 6, and/or 7. Grassland losses would likely occur in the vicinity of Cache Slough, on
Decker Island in the West Delta ROA, on the upslope fringes of Suisun Marsh, and along narrow
bands adjacent to waterways in the South Delta ROA. Tidal restoration would directly impact
and fragment grassland just north of Rio Vista in and around French and Prospect Islands, and in
an area south of Rio Vista around Three-mile Slough. Losses of alkali seasonal wetland complex
habitat would likely occur in the south end of the Yolo Bypass and on the northern fringes of
Suisun Marsh.

- **CM5 Seasonally Inundated Floodplain Restoration:** Construction of setback levees to restore
seasonally inundated floodplain would permanently and temporarily remove approximately
1,450 acres of modeled golden eagle and ferruginous hawk foraging habitat (933 permanent,
517 temporary). These losses would be expected after the first 10 years of Alternative 1B
implementation along the San Joaquin River and other major waterways in CZ 7.

- **CM8 Grassland Natural Community Restoration and CM9 Vernal Pool and Alkali Seasonal Wetland
Complex Restoration:** Temporary construction-related disturbance of grassland habitat would
result from implementation of CM8 and CM9 in in CZs 1, 2, 4, 5, 7, 8, and 11. However, all areas
would be restored after the construction periods. Grassland restoration would be implemented
on agricultural lands that also provide foraging habitat for golden eagle and ferruginous hawk
and would result in the conversion of 837 acres of cultivated lands to grassland.

- **CM10 Nontidal Marsh Restoration:** Implementation of CM10 Nontidal Marsh Restoration would
result in the permanent removal of 705 acres of golden eagle and ferruginous hawk foraging
habitat.

- **CM11 Natural Communities Enhancement and Management:** A variety of habitat management
actions included in CM11 that are designed to enhance wildlife values in restored or protected
habitats could result in localized ground disturbances that could temporarily remove small
amounts of golden eagle and ferruginous hawk foraging habitat. Ground-disturbing activities,
such as removal of nonnative vegetation and road and other infrastructure maintenance
activities, would be expected to have minor adverse effects on available habitat for these species. CM11 would also include the construction of recreational-related facilities including trails, interpretive signs, and picnic tables (BDCP Chapter 4, Covered Activities and Associated Federal Actions). The construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible. However, approximately 50 acres of grassland habitat would be lost from the construction of trails and facilities.

- **CM18 Conservation Hatcheries:** Implementation of CM18 would remove up to 35 acres of modeled golden eagle and ferruginous hawk foraging habitat for the development of a delta and longfin smelt conservation hatchery in CZ 1.

- **Operations and Maintenance:** Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect golden eagle and ferruginous hawk use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7 and conservation actions as described below.

- **Injury and Direct Mortality:** Construction would not be expected to result in direct mortality of golden eagle and ferruginous hawk because foraging individuals would be expected to temporarily avoid the increased noise and activity associated with construction areas.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

**Near-Term Timeframe**

Because the water conveyance facility construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of such conveyance facility construction would not be adverse under NEPA. The Plan would remove 13,316 acres (8,412 permanent, 4,904 temporary) of modeled golden eagle and ferruginous hawk foraging habitat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 7,490 acres), and implementing other conservation measures (CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, CM7 Riparian Natural Community Restoration, CM8 Grassland Natural Community Restoration, CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration, CM11 Natural Communities Enhancement and Management and CM18 Conservation Hatcheries—5,826 acres).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 for protection of habitat. Using this ratio would indicate that 14,980 acres should be protected to compensate for the CM1 losses of 7,490 acres of golden eagle and ferruginous hawk foraging habitat. The near-term effects of other conservation actions would remove 5,826 acres of modeled habitat, and therefore require 11,652 acres of protection of golden eagle and ferruginous hawk habitat using the same typical NEPA and CEQA ratio (2:1 for protection).

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,400 acres of non-rice cultivated lands (Table 3-4...
in Chapter 3). These conservation actions are associated with CM3, CM8, and CM9 and would occur in the same timeframe as the construction and early restoration losses thereby avoiding adverse effects of habitat loss on golden eagle and ferruginous hawk foraging in the study area. Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand golden eagle and ferruginous hawk foraging habitat and reduce the effects of current levels of habitat fragmentation. Under **CM11 Natural Communities Enhancement and Management**, insect and mammal prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Burrow availability would be increased on protected natural communities by encouraging ground squirrel occupancy and expansion through the creation of berms, mounds, edges, and through the prohibition of ground squirrel control programs (i.e., poisoning).

Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential foraging habitat for golden eagle and ferruginous hawk (Objective CLNC1.1). Approximately 87% of cultivated lands protected by the late long-term time period would be in alfalfa and pasture crop types (very high- and high-value crop types for Swainson’s hawk (Objective SH1.2) which are also suitable for golden eagle and ferruginous hawk. This biological objective provides an estimate for the high proportion of cultivated lands protected in the near-term time period which would be suitable for golden eagle and ferruginous hawk.

The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on golden eagle and ferruginous hawk. However, the conservation commitment is 7,572 acres short of meeting the compensation for other near-term effects on golden eagle and ferruginous hawk habitat. Mitigation Measure BIO-113, **Compensate for the Near-Term Loss of Golden Eagle and Ferruginous Hawk Foraging Habitat** would be available to address the adverse effect of near-term habitat loss.

The Plan also includes commitments to implement **AMM1 Worker Awareness Training**, **AMM2 Construction Best Management Practices and Monitoring**, **AMM3 Stormwater Pollution Prevention Plan**, **AMM4 Erosion and Sediment Control Plan**, **AMM5 Spill Prevention, Containment, and Countermeasure Plan**, **AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material**, and **AMM7 Barge Operations Plan**. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, **Avoidance and Minimization Measures**.

### Late Long-Term Timeframe

Based on modeled habitat, the study area supports approximately 269,411 acres of modeled foraging habitat for golden eagle and ferruginous hawk. Alternative 1B as a whole would result in the permanent loss of and temporary effects on 34,631 acres of modeled foraging habitat during the term of the Plan (13% of the modeled habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures.

The Plan includes conservation commitments through **CM3 Natural Communities Protection and Restoration**, **CM8 Grassland Natural Community Restoration**, and **CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration** to protect 8,000 acres and restore 2,000 acres of grassland natural
community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3, Description of Alternatives). Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand foraging habitat for golden eagle and ferruginous hawk and reduce the effects of current levels of habitat fragmentation. Under CM11 Natural Communities Enhancement and Management, insect and small mammal prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Burrow availability would be increased through the creation of berms, mounds, edges, and through the prohibition of ground squirrel control programs (i.e., poisoning). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential habitat for golden eagle and ferruginous hawk (Objective CLNC1.1). Approximately 42,275 acres of cultivated lands protected would be in alfalfa and pasture crop types (very high- and high-value crop types for Swainson's hawk (Objective SH1.2) which are also suitable for golden eagle and ferruginous hawk.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.

**NEPA Effects:** The loss of golden eagle and ferruginous hawk habitat and potential for mortality of this special-status species under Alternative 1B would represent an adverse effect in the absence of other conservation actions. However, with habitat protection and restoration associated with CM3, CM8, CM9, and CM11, guided by biological goals and objectives and by AMM1–AMM7, which would be in place throughout the construction period, and Mitigation Measure BIO-113, Compensate for the Near-Term Loss of Golden Eagle and Ferruginous Hawk Foraging Habitat, the effects of habitat loss and potential direct mortality on golden eagle and ferruginous hawk under Alternative 1B would not be adverse.

**CEQA Conclusion:**

**Near-Term Timeframe**

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. The Plan would remove 13,316 acres (8,412 permanent, 4,904 temporary) of modeled golden eagle and ferruginous hawk foraging habitat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 7,490 acres), and implementing other conservation measures (CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, CM7 Riparian Natural Community Restoration, CM8 Grassland Natural Community Restoration, CM9 Vernal Pool and
Alternative 1B  
Terrestrial Biological Resources

Alkaline Seasonal Wetland Complex Restoration, CM11 Natural Communities Enhancement and Management and CM18 Conservation Hatcheries—5,826 acres.

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 for protection of habitat. Using this ratio would indicate that 14,980 acres should be protected to compensate for the CM1 losses of 7,490 acres of golden eagle and ferruginous hawk foraging habitat. The near-term effects of other conservation actions would remove 5,826 acres of modeled habitat, and therefore require 11,652 acres of protection of golden eagle and ferruginous hawk habitat using the same typical NEPA and CEQA ratio (2:1 for protection).

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,400 acres of non-rice cultivated lands (Table 3-4 in Chapter 3). These conservation actions are associated with CM3, CM8, and CM9 and would occur in the same timeframe as the construction and early restoration losses thereby avoiding significant impacts of habitat loss on golden eagle and ferruginous hawk foraging in the study area. Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand golden eagle and ferruginous hawk foraging habitat and reduce the effects of current levels of habitat fragmentation. Under CM11 Natural Communities Enhancement and Management, insect and mammal prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Burrow availability would be increased on protected natural communities by encouraging ground squirrel occupancy and expansion through the creation of berms, mounds, edges, and through the prohibition of ground squirrel control programs (i.e., poisoning). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential foraging habitat for golden eagle and ferruginous hawk (Objective CLNC1.1). Approximately 87% of cultivated lands protected by the late long-term time period would be in alfalfa and pasture crop types (very high- and high-value crop types for Swainson’s hawk (Objective SH1.2) which are also suitable for golden eagle and ferruginous hawk. This biological objective provides an estimate for the high proportion of cultivated lands protected in the near-term time period which would be suitable for golden eagle and ferruginous hawk.

The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on golden eagle and ferruginous hawk. However, the conservation commitment is 7,572 acres short of meeting the compensation for other near-term effects on golden eagle and ferruginous hawk habitat. The implementation of Mitigation Measure BIO-113, Compensate for the Near-Term Loss of Golden Eagle and Ferruginous Habitat, would reduce the near-term impact of habitat loss to a less-than-significant level.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or
minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*.

**Late Long-Term Timeframe**

Based on modeled habitat, the study area supports approximately 269,411 acres of modeled foraging habitat for golden eagle and ferruginous hawk. Alternative 1B as a whole would result in the permanent loss of and temporary effects on 34,631 acres of modeled foraging habitat during the term of the Plan (13% of the modeled habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures.

The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM8 Grassland Natural Community Restoration, and CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration* to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3). Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand foraging habitat for golden eagle and ferruginous hawk and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect and small mammal prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Burrow availability would be increased on protected natural communities by encouraging ground squirrel occupancy and expansion through the creation of berms, mounds, edges, and through the prohibition of ground squirrel control programs (i.e., poisoning). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential habitat for golden eagle and ferruginous hawk (Objective CLNC1.1). Approximately 42,275 acres of cultivated lands protected would be in alfalfa and pasture crop types. These are very high- and high-value crop types for Swainson's hawk (Objective SH1.2) which are also suitable for golden eagle and ferruginous hawk.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*.

Considering Alternative 1B’s protection and restoration provisions, which would provide acreages of new high-value or enhanced habitat in amounts suitable to compensate for habitats lost to construction and restoration activities, and with the implementation of AMM1–AMM7 and Mitigation Measure BIO-113, *Compensate for the Near-Term Loss of Golden Eagle and Ferruginous Hawk Foraging Habitat*, the loss of habitat or direct mortality through implementation of Alternative 1B would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of either species. Therefore, the loss of habitat
or potential mortality under this alternative would have a less-than-significant impact on golden eagle and ferruginous hawk.

**Mitigation Measure BIO-113: Compensate for the Near-Term Loss of Golden Eagle and Ferruginous Hawk Foraging Habitat**

DWR will manage and protect sufficient acres of cultivated lands such as pasture, grain and hay crops, or alfalfa to provide golden eagle and ferruginous hawk foraging habitat such that the total acres of high-value habitat impacted in the near-term timeframe are mitigated at a ratio of 2:1. Additional grassland protection, enhancement, and management may be substituted for the protection of high-value cultivated lands.

**Impact BIO-114: Effects on Golden Eagle and Ferruginous Hawk Associated with Electrical Transmission Facilities**

New transmission lines would increase the risk that golden eagles and ferruginous hawks could be subject to power line strikes, which could result in injury or mortality of these species. Golden eagle and ferruginous hawk would be at low risk of bird strike mortality based on factors assessed in the bird strike vulnerability analysis (BDCP Attachment 5.J.C, *Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines*). Factors analyzed include the height of the new transmission lines and the flight behavior of species. The existing network of transmission lines in the Plan Area currently poses the same small risk for golden eagle and ferruginous hawk, and any incremental risk associated with the new power line corridors would also be expected to be low. *AMM20 Greater Sandhill Crane* would further reduce any adverse effects.

**NEPA Effects:** New transmission lines would minimally increase the risk for golden eagle and ferruginous hawk power line strikes. With the implementation of *AMM20 Greater Sandhill Crane*, the potential effect of the construction of new transmission lines on golden eagle and ferruginous hawk would not be adverse.

**CEQA Conclusion:** New transmission lines would minimally increase the risk for golden eagle and ferruginous hawk power line strikes. *AMM20 Greater Sandhill Crane* would reduce the potential impact of the construction of new transmission lines on golden eagle and ferruginous hawk to a less-than-significant level.

**Impact BIO-115: Indirect Effects of Plan Implementation on Golden Eagle and Ferruginous Hawk**

**Indirect construction- and operation-related effects:** Construction- and subsequent maintenance-related noise and visual disturbances could disrupt foraging, and reduce the functions of suitable foraging habitat for golden eagle and ferruginous hawk. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5.J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect golden eagle or ferruginous hawk. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring,*
would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to golden eagle and ferruginous hawk grassland habitat could also have a negative effect on the species. However, AMM1–AMM7 would also ensure that measures would be in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

**NEPA Effects:** Indirect effects on golden eagle and ferruginous hawk as a result of Alternative 1B implementation could have adverse effects on these species through the modification of habitat. With the incorporation of AMM1–AMM7 into the BDCP, indirect effects as a result of Alternative 1B implementation would not have an adverse effect on golden eagle and ferruginous hawk.

**CEQA Conclusion:** Indirect effects on golden eagle and ferruginous hawk as a result of Alternative 1B implementation could have a significant impact on the species from modification of habitat. With the incorporation of AMM1–AMM7 into the BDCP, indirect effects as a result of Alternative 1B implementation would have a less-than-significant impact on golden eagle and ferruginous hawk.

**Impact BIO-116: Periodic Effects of Inundation on Golden Eagle and Ferruginous Hawk Habitat as a Result of Implementation of Conservation Components**

Flooding of the Yolo Bypass from Fremont Weir operations (*CM2 Yolo Bypass Fisheries Enhancement*) would increase the frequency and duration of inundation on approximately 1,158–3,650 acres of modeled golden eagle and ferruginous hawk foraging habitat (Table 12-1B-44).

Based on hypothetical footprints, implementation of *CM5 Seasonally Inundated Floodplain Restoration* could result in the periodic inundation of up to approximately 3,823 acres of modeled habitat (Table 12-1B-44).

Golden eagles and ferruginous hawks would not likely use inundated areas for foraging, and increased frequency and duration of inundation of grassland habitats may affect prey populations that have insufficient time to recover following inundation events. However, periodically inundated habitat would not be expected to have an adverse effect on local or migratory golden eagles or the wintering ferruginous hawk populations in the study area.

**NEPA Effects:** Implementation of CM2 would increase the frequency and duration of inundation on approximately 1,158–3,650 acres of modeled golden eagle and ferruginous hawk foraging habitat. In addition, implementation of CM5 could result in the periodic inundation of up to 3,823 acres of modeled habitat. However, periodic inundation would not be expected to have an adverse effect on the wintering golden eagle or ferruginous hawk populations in the study area.

**CEQA Conclusion:** Implementation of CM2 would increase the frequency and duration of inundation on approximately 1,158–3,650 acres of modeled golden eagle and ferruginous hawk foraging habitat. In addition, implementation of CM5 could result in the periodic inundation of up to 3,823 acres of modeled habitat. However, periodic inundation would be expected to have a less-than-significant impact on the golden eagle and ferruginous hawk populations in the study area.

**Cormorants, Herons and Egrets**

This section describes the effects of Alternative 1B, including water conveyance facilities construction and implementation of other conservation components, on double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron. Modeled breeding habitat for these species consists of valley/foothill riparian forest.
Construction and restoration associated with Alternative 1B conservation measures would result in both temporary and permanent losses of cormorant, heron, and egret modeled habitat as indicated in Table 12-1B-45. The majority of the losses would take place over an extended period of time as tidal marsh is restored in the study area. Although restoration for the loss of nesting habitat would be initiated in the same timeframe as the losses, it could take one or more decades for restored habitats to replace the functions of habitat lost. This time lag between impacts and restoration of habitat function would be minimized by specific requirements of AMM18 Swainson’s Hawk and White-Tailed Kite, including the planting of mature trees in the near-term time period. Full implementation of Alternative 1B would include the following conservation actions over the term of the BDCP which would also benefit cormorants, herons, and egrets (BDCP Chapter 3, Section 3.3, Biological Goals and Objectives).

- Restore or create at least 5,000 acres of valley/foothill riparian natural community, with at least 3,000 acres occurring on restored seasonally inundated floodplain (Objective VFRNC1.1, associated with CM7).
- Protect at least 750 acres of existing valley/foothill riparian natural community in CZ 7 by year 10 (Objective VFRNC1.2, associated with CM3).
- Maintain and protect the small patches of important wildlife habitats associated with cultivated lands within the reserve system including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Objective CLNC1.3, associated with CM3).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities to enhance natural communities for species and implementation of AMM1–AMM7, AMM18 Swainson’s Hawk and White-Tailed Kite, and Mitigation Measure BIO-75, impacts on cormorants, herons, and egrets would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

a See Appendix 12E for detailed breakdown of conservation measure effects over the BDCP’s near-term and late long-term timeframes.
b See discussion below for a description of applicable CMs.
c LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
d Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

Impact BIO-117: Loss or Conversion of Nesting Habitat for and Direct Mortality of Cormorants, Herons and Egrets

Alternative 1B conservation measures would result in the combined permanent and temporary loss of up to 897 acres of modeled nesting habitat (735 acres of permanent loss and 162 acres of temporary loss) for double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron (Table 12-1B-45). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Fremont Weir/Yolo Bypass fisheries improvements (CM2), tidal natural communities restoration (CM4), and seasonally inundated floodplain restoration (CM5). Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate cormorant, heron, and egret modeled habitat. Each of these individual activities is described below. A summary statement of the combined impacts, NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.

- **CM1 Water Facilities and Operation:** Construction of Alternative 1B water conveyance facilities would result in the combined permanent and temporary loss of up to 90 acres of modeled nesting habitat for cormorants, herons, and egrets (Table 12-1B-45). Of the 90 acres of modeled habitat that would be removed for the construction of the conveyance facilities, 51 acres would be a permanent loss and 39 acres would be a temporary loss of habitat. This loss would have the potential to displace individuals, if present, and remove the functions and value of potentially
suitable habitat. The habitat would be removed at multiple locations from the north Delta to the east Delta and in the vicinity of Clifton Court Forebay. Almost all of the losses would occur on the borders of waterways. In the north Delta, most of the permanent loss would occur where Intakes 1–5 encroach on the Sacramento River’s east bank between Freeport and Courtland. The riparian areas here are very small patches, some dominated by valley oak and others by nonnative trees and scrub vegetation. In the east Delta, small permanent losses would occur from canal construction just south of Twin Cities Road and just north of Walnut Grove Road. A small area of riparian habitat (mostly blackberries) would be permanently removed in the south Delta at the new forebay construction site. The temporary riparian losses would occur at the intake sites along the Sacramento River and at temporary siphon work areas where the canal would cross Beaver Slough, Hog Slough, Sycamore Slough, White Slough, Disappointment Slough, Railroad Canal, and Middle River just south of Victoria Canal. Tunnel construction at Old River just south of Victoria Canal would also temporarily remove mixed willows and brambles. There are no occurrences of least Bell’s vireo or yellow warbler that intersect with the CM1 footprint. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 1B construction locations.

The primary impact of concern regarding double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron is the loss of existing known nest trees, and other large trees associated with known nest sites. There is one great egret rookery that is currently intersected by a temporary siphon work area associated with CM1. The location of the rookery is on an inchannel island, north of Union Island and south of the town of Holt. Because the species is highly traditional in their use of rookeries, the establishment of new nest sites is unpredictable. Therefore, to avoid adverse effects on great blue herons (and cormorants, herons, and egrets), should future surveys detect additional rookeries, existing rookeries must be avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and Mitigation Measure BIO-117, *Avoid Impacts on Rookeries*, would be available to address this adverse effect on cormorants, herons, and egrets. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 1B construction locations.

- **CM2 Yolo Bypass Fisheries Enhancement:** Construction of the Yolo bypass fisheries enhancement would result in the combined permanent and temporary loss of up to 177 acres of nesting habitat (89 acres of permanent loss, 88 acres of temporary loss) in the Yolo Bypass in CZ 2. Activities through CM2 could involve excavation and grading in valley/foothill riparian areas to improve passage of fish through the bypasses. Most of the riparian losses would occur at the north end of Yolo Bypass where major fish passage improvements are planned. Excavation to improve water movement in the Toe Drain and in the Sacramento Weir would also remove potential nesting habitat. The loss is expected to occur during the first 10 years of Alternative 1B implementation.

- **CM4 Tidal Natural Communities Restoration:** Tidal habitat restoration (CM4) site preparation and inundation would permanently remove an estimated 552 acres of nesting habitat for cormorants, herons and egrets. Trees would not be actively removed but tree mortality would be expected over time as areas became tidally inundated. Depending on the extent and value of remaining habitat, this could reduce use of these habitats by these species. There is one CNDDB occurrence of a great blue heron rookery that overlaps with the hypothetical restoration footprint for tidal restoration. The occurrence is on Decker Island and tidal restoration could potentially impact the nest trees from inundation. This potential effect would need to be addressed within the project-specific analysis for tidal restoration projects.
- **CM5 Seasonally Inundated Floodplain Restoration**: Construction of setback levees to restore seasonally inundated floodplain would permanently remove approximately 43 acres and temporarily remove approximately 35 acres of potential cormorant, heron, and egret nesting habitat. These losses would be expected after the first 10 years of Alternative 1B implementation along the San Joaquin River and other major waterways in CZ 7.

- **CM11 Natural Communities Enhancement and Management**: Habitat management- and enhancement-related activities could disturb cormorant, heron, and egret nests if they were present near work sites. A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in BDCP-protected habitats may result in localized ground disturbances that could temporarily remove small amounts of cormorant, heron, and egret habitat and reduce the functions of habitat until restoration is complete. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance, are expected to have minor effects on available habitat for these species and are expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below.

- Permanent and temporary habitat losses from the above conservation measures would primarily consist of fragmented riparian stands. Temporarily affected areas would be restored as riparian habitat within 1 year following completion of construction activities. Although the effects are considered temporary, the restored riparian habitat would require years to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure for established rookeries. **AMM18 Swainson’s Hawk and White-Tailed Kite** contains actions described below to reduce the effect of temporal loss of mature riparian habitat, including the transplanting of mature trees.

- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect use of the surrounding habitat by cormorants, herons or egrets. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs and conservation actions as described below.

- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron if they were present in the Plan Area, because they would be expected to avoid contact with construction and other equipment. If birds were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could affect nests or lead to their abandonment, potentially resulting in mortality of eggs and nestlings. Because cormorants, herons and egrets are highly traditional in their use of nest sites, all disturbance to nesting birds must be avoided or minimized. Mitigation Measure BIO-75, **Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds**, and Mitigation Measure BIO-117, **Avoid Impacts on Rookeries**, would be available to address these adverse effects on cormorants, herons, and egrets.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.
**Near-Term Timeframe**

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. The Plan would remove 565 acres of nesting habitat for cormorants, herons, and egrets in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 90 acres of nesting habitat), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, and CM5 Seasonally Inundated Floodplain Restoration*—475 acres of nesting habitat).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat for breeding habitat. Using these ratios would indicate that 90 acres of breeding habitat should be restored/created and 90 acres should be protected to compensate for the CM1 losses of modeled cormorant, heron, and egret habitat. In addition, the near-term effects of other conservation actions would remove 475 acres of modeled breeding habitat, and therefore require 475 acres of restoration and 475 acres of protection of modeled cormorant, heron, and egret habitat using the same typical NEPA and CEQA ratios.

The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, Conservation Strategy). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for these species. In addition, small but essential nesting habitat associated with cultivated lands would also be maintained and protected such as isolated trees, tree rows along field borders or roads, or small clusters of trees in farmyards or at rural residences (Objective CLNC1.3).

The 750 acres of protection and 800 acres of restoration contained in the near-term Plan goals satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1 and other near-term impacts on cormorant, heron, and egret nesting habitat. The 800 acres of restored riparian habitat would be initiated in the near-term to offset the loss of potential nesting habitat, but would require years to several decades to functionally replace habitat that has been affected and for trees to attain sufficient size and structure suitable for established rookeries. This time lag between the removal and restoration of nesting habitat could have a substantial impact on cormorants, herons and egrets in the near-term time period.

*AMM18 Swainson’s Hawk and White-Tailed Kite* would implement a program to plant large mature trees, including transplanting trees scheduled for removal. These would be supplemented with additional saplings and would be expected to reduce the temporal effects of loss of nesting habitat. The plantings would occur prior to or concurrent with (in the case of transplanting) the loss of trees. In addition, at least five trees (5-gallon container size) would be planted within the BDCP reserve system for every tree 20 feet or taller anticipated to be removed by construction during the near-term period. A variety of native tree species would be planted to provide trees with differing growth rates, maturation, and life span. Replacement trees that were incorporated into the riparian restoration would not be clustered in a single region of the study area, but would be distributed throughout protected lands.
The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures. Double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron are not species that are covered under the BDCP. For the BDCP to avoid having an adverse effect on individuals, existing nests and rookeries would have to be avoided. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would be available to address adverse effects on nesting cormorants, herons, and egrets.

Late Long-Term Timeframe

Based on modeled habitat, the study area supports approximately 17,966 acres of modeled nesting habitat for cormorants, herons, and egrets. Alternative 1B as a whole would result in the permanent loss of and temporary effects on 897 acres of potential breeding habitat (5% of the potential breeding habitat in the Plan Area).

The Plan includes conservation commitments through CM3 Natural Communities Protection and Restoration, CM5 Seasonally Inundated Floodplain Restoration, and CM7 Riparian Natural Community Restoration to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill riparian natural community (Table 3-4 in Chapter 3). The majority of riparian protection and restoration acres would occur in CZ.7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, Conservation Strategy). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for riparian species. The Plan’s objectives would also benefit cormorants, herons, and egrets by protecting small but essential habitats that occur within cultivated lands, such as tree rows along field borders or roads, and small clusters of trees in farmyards or rural residences (Objective CLNC1.3). In addition, the distribution and abundance of potential nest trees would be increased by planting and maintaining native trees along roadsides and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SWHA2.1).

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures. Double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron are not species that are covered under the BDCP. These species are highly traditional in their use of nest sites, and for the BDCP to avoid having an adverse effect on individuals, preconstruction surveys would be required to ensure that nests are detected and any direct and indirect impacts on rookeries are avoided. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, and Mitigation Measure BIO-117, Avoid Impacts on Rookeries, would be available to address adverse effects on nesting cormorants, herons, and egrets.
**NEPA Effects:** The loss of cormorant, heron, and egret habitat and potential for direct mortality of these special-status species under Alternative 1B would represent an adverse effect in the absence of other conservation actions. However, with habitat protection and restoration associated with CM3, CM5, CM7, CM8, CM9, and CM11, guided by biological goals and objectives and by AMM1–AMM7 and AMM18 Swainson’s Hawk and White-Tailed Kite, which would be in place throughout the construction period, the effects of habitat loss on cormorants, herons, and egrets under Alternative 1B would not be adverse. Double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron are not species that are covered under the BDCP. For the BDCP to avoid effects on these species, preconstruction surveys for noncovered species would be necessary to ensure that nests are detected and avoided. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, and Mitigation Measure BIO-117, Avoid Impacts on Rookeries, would be available to address adverse effects on nesting cormorants, herons, and egrets.

**CEQA Conclusion:**

**Near-Term Timeframe**

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under NEPA. The Plan would remove 565 acres of nesting habitat for cormorants, herons, and egrets in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 90 acres of nesting habitat), and implementing other conservation measures (CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, and CM5 Seasonally Inundated Floodplain Restoration—475 acres of nesting habitat).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 would be 1:1 for restoration/creation and 1:1 protection of valley/foothill riparian habitat for breeding habitat. Using these ratios would indicate that 90 acres of breeding habitat should be restored/created and 90 acres should be protected to compensate for the CM1 losses of modeled cormorant, heron, and egret habitat. In addition, the near-term effects of other conservation actions would remove 475 acres of modeled breeding habitat, and therefore require 475 acres of restoration and 475 acres of protection of modeled cormorant, heron, and egret habitat using the same typical NEPA and CEQA ratios.

The majority of riparian protection and restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, Conservation Strategy). Riparian restoration would expand the patches of existing riparian forest in order to support nesting habitat for these species. In addition, small but essential nesting habitat associated with cultivated lands would also be maintained and protected such as isolated trees, tree rows along field borders or roads, or small clusters of trees in farmyards or at rural residences (Objective CLNC1.3).

The 750 acres of protection and 800 acres of restoration contained in the near-term Plan goals satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1 and other near-term impacts on cormorant, heron, and egret nesting habitat. The 800 acres of restored riparian habitat would be initiated in the near-term to offset the loss of potential nesting habitat, but would require years to several decades to functionally replace habitat that has been affected and for
trees to attain sufficient size and structure suitable for established rookeries. This time lag between
the removal and restoration of nesting habitat could have a substantial impact on cormorants,
herons and egrets in the near-term time period.

AMM18 Swainson's Hawk and White-Tailed Kite would implement a program to plant large mature
trees, including transplanting trees scheduled for removal. These would be supplemented with
additional saplings and would be expected to reduce the temporal effects of loss of nesting habitat.
The plantings would occur prior to or concurrent with (in the case of transplanting) the loss of trees.
In addition, at least five trees (5-gallon container size) would be planted within the BDCP reserve
system for every tree 20 feet or taller anticipated to be removed by construction during the near-
term period. A variety of native tree species would be planted to provide trees with differing growth
rates, maturation, and life span. Replacement trees that were incorporated into the riparian
restoration would not be clustered in a single region of the study area, but would be distributed
throughout protected lands.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2
Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention
Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and
Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged
Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or
minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are
described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures. Double-crested
cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron are not
species that are covered under the BDCP. For the BDCP to avoid an adverse effect on individuals,
preconstruction surveys for noncovered avian species would be required to ensure that nests are
detected and avoided. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and
Avoid Disturbance of Nesting Birds, would reduce this potential impact to a less-than-significant
level.

Late Long-Term Timeframe

Based on modeled habitat, the study area supports approximately 17,966 acres of modeled nesting
habitat for cormorants, herons, and egrets. Alternative 1B as a whole would result in the permanent
loss of and temporary effects on 897 acres of potential breeding habitat (5% of the potential
breeding habitat in the Plan Area).

The Plan includes conservation commitments through CM3 Natural Communities Protection and
Restoration, CM5 Seasonally Inundated Floodplain Restoration, and CM7 Riparian Natural Community
Restoration to restore or create at least 5,000 acres and protect at least 750 acres of valley/foothill
riparian natural community (Table 3-4 in Chapter 3). The majority of riparian protection and
restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large
patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP
Chapter 3, Conservation Strategy). Riparian restoration would expand the patches of existing
riparian forest in order to support nesting habitat for riparian species. The Plan’s objectives would
also benefit cormorants, herons, and egrets by protecting small but essential habitats that occur
within cultivated lands, such as tree rows along field borders or roads, and small clusters of trees in
farmyards or rural residences (Objective CLNC1.3). In addition, the distribution and abundance of
potential nest trees would be increased by planting and maintaining native trees along roadsides
and field borders within protected cultivated lands at a rate of one tree per 10 acres (Objective SWHA2.1).

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures. Double-crested cormorant, great blue heron, great egret, snowy egret, and black-crowned night heron are not species that are covered under the BDCP. These species are highly traditional in their use of nest sites, and for the BDCP to avoid a significant impact on individuals, preconstruction surveys would be required to ensure that nests are detected and any direct and indirect impacts on rookeries are avoided. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, and Mitigation Measure BIO-117, Avoid Impacts on Rookeries, would reduce this potential impact to a less-than-significant level.

Considering these protection and restoration provisions, which would provide acreages of new or enhanced habitat in amounts sufficient to compensate for the loss of riparian habitats lost to construction and restoration activities, and with implementation of AMM1–AMM7, AMM18 Swainson’s Hawk and White-Tailed Kite, and Mitigation Measures BIO-75 and BIO-117, the loss of habitat or direct mortality through implementation of Alternative 1B would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of these species. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on cormorants, herons, and egrets.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Mitigation Measure BIO-117: Avoid Impacts on Rookeries

Herons, egrets, and cormorants are highly traditional in their use of nest sites (rookeries); therefore, DWR will avoid all direct and indirect impacts on rookeries.

Impact BIO-118: Effects Associated with Electrical Transmission Facilities on Cormorants, Herons and Egrets

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of cormorants, herons and egrets. AMM20 Greater Sandhill Crane would minimize the risk for bird-power line strikes, for these species. This measure would ensure that conductor and ground lines are fitted with flight diverters in compliance with the best available practices, such as those specified in the USFWS Avian Protection Guidelines and would minimize the potential for an adverse effect.

NEPA Effects: New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of cormorants, herons, and egrets. AMM20 Greater Sandhill Crane would reduce the potential for collisions on new and select existing powerlines in the study area.
The construction of new transmission lines would not result in an adverse effect on cormorants, herons, and egrets.

**CEQA Conclusion:** New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of cormorants, herons, and egrets. AMM20 Greater Sandhill Crane would reduce birdstrike on new transmission lines and select existing transmission lines with the installation of flight diverters. With these in place, new transmission lines would have a less-than-significant impact on cormorants, herons and egrets.

**Impact BIO-119: Indirect Effects of Plan Implementation on Cormorants, Herons and Egrets**

**Indirect construction- and operation-related effects:** Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.1, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect cormorants, herons, or egrets. If cormorants, herons or egrets were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would avoid the potential for adverse effects of construction-related activities on survival and productivity of nesting cormorants, herons or egrets. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect cormorants, herons or egrets in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to suitable habitat could also have an adverse effect on these species. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills and ensure that measures are in place to prevent runoff from the construction area and negative effects of dust on active nests.

**Methylmercury Exposure:** Covered activities have the potential to exacerbate bioaccumulation of mercury in avian species, including cormorants, herons or egrets. Future operational impacts under CM1 were analyzed using a DSM-2 based model to assess potential effects on mercury concentration and bioavailability resulting from proposed flows. Subsequently, a regression model was used to estimate fish-tissue concentrations under these future operational conditions (evaluated starting operations or ESO). Results indicated that changes in total mercury levels in water and fish tissues due to ESO were insignificant (see BDCP Appendix 5.D, Tables 5D.4-3, 5D.4-4, and 5D.4-5).

Marsh (tidal and nontidal) and floodplain restoration have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community and floodplain restoration could indirectly effect on cormorants, herons or egrets, via uptake in lower tropic levels (as described in the BDCP, Appendix 5.D, *Contaminants*).

In addition, the potential mobilization or creation of methylmercury within the Plan Area varies with site-specific conditions and would need to be assessed at the project level. *CM12 Methylmercury Management* contains provisions for project-specific Mercury Management Plans. Site-specific
restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would be available to address the uncertainty of methylmercury levels in restored tidal marsh and potential impacts on cormorants, herons or egrets.

**Selenium Exposure:** Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher levels of selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including cormorants, herons, and egrets. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4 and CM5) would lead to adverse effects on cormorants, herons, and egrets.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on cormorants, herons, and egrets from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of AMM27 *Selenium Management* (BDCP Appendix 3.C, *Avoidance and Minimization Measures*) which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This
avoidance and minimization measure would be implemented as part of the tidal habitat restoration
design schedule.

**NEPA Effects:** Noise and visual disturbances from the construction of water conveyance facilities
could reduce cormorant, heron, and egret use of modeled habitat adjacent to work areas. Moreover,
operation and maintenance of the water conveyance facilities, including the transmission facilities,
could result in ongoing but periodic postconstruction disturbances that could affect cormorant,
heron, and egret use of the surrounding habitat. Mitigation Measure BIO-75, *Conduct Preconstruction
Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and Mitigation Measure BIO-117, *Avoid
Impacts on Rookeries*, would be available to address adverse effects on nesting individuals in
addition to AMM1–AMM7. Tidal habitat restoration could result in increased exposure of
cormorants, herons, and egrets to selenium. This effect would be addressed through the
implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat
restoration design elements to reduce the potential for bioaccumulation of selenium and its
bioavailability in tidal habitats. The implementation of tidal natural communities restoration or
floodplain restoration could result in increased exposure of cormorants, herons or egrets to
methylmercury through the ingestion of fish in restored tidal areas. However, it is unknown what
concentrations of methylmercury are harmful to these species and the potential for increased
exposure varies substantially within the study area. Site-specific restoration plans that address the
creation and mobilization of mercury, as well as monitoring and adaptive management as described
in CM12, would address the uncertainty of methylmercury levels in restored tidal marsh in the study
area and better inform potential impacts on cormorants, herons, and egrets. The site-specific
planning phase of marsh restoration would be the appropriate place to assess the potential for risk
of methylmercury exposure for cormorants, herons, and egrets once site specific sampling and other
information could be developed.

**CEQA Conclusion:** Impacts of noise, the potential for hazardous spills, increased dust and
sedimentation, and operations and maintenance of the water conveyance facilities would be less
than significant with the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction
Impacts on Rookeries*, and AMM1–AMM7. The implementation of tidal natural communities
restoration or floodplain restoration could result in increased exposure of cormorants, herons or
egrets to methylmercury, through the ingestion of fish in tidally restored areas. However, it is
unknown what concentrations of methylmercury are harmful to these species. Site-specific
restoration plans that address the creation and mobilization of mercury, as well as monitoring and
adaptive management as described in CM12 would address the potential impacts of methylmercury
levels in restored tidal marsh in the study area on cormorants, herons, and egrets. Tidal habitat
restoration could result in increased exposure of cormorants, herons, and egrets to selenium. This
effect would be addressed through the implementation of *AMM27 Selenium Management*, which
would provide specific tidal habitat restoration design elements to reduce the potential for
bioaccumulation of selenium and its bioavailability in tidal habitats. Therefore, the indirect effects of
Alternative 1B implementation would not have an adverse effect on cormorants, herons, and egrets.

**Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid
Disturbance of Nesting Birds**

See Mitigation Measure BIO-75 under Impact BIO-75.
Mitigation Measure BIO-117: Avoid Impacts on Rookeries

Herons, egrets, and cormorants are highly traditional in their use of nest sites (rookeries); therefore, DWR will avoid all direct and indirect impacts on rookeries.

Impact BIO-120: Periodic Effects of Inundation on Cormorants, Herons and Egrets as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from Fremont Weir operations (CM2) would increase the frequency and duration of inundation of approximately 51–92 acres of modeled breeding habitat for cormorants, herons and egrets. However, increased periodic flooding is not expected to cause any adverse effect on breeding habitat because trees in which nest sites are situated already withstand floods, the increase in inundation frequency and duration is expected to remain within the range of tolerance of riparian trees, and nest sites are located above floodwaters.

Based on hypothetical floodplain restoration, CM5 implementation could result in periodic inundation of up to 266 acres of breeding habitat for cormorants, herons and egrets. The overall effect of seasonal inundation in existing riparian natural communities is likely to be beneficial for these species, because, historically, flooding was the main natural disturbance regulating ecological processes in riparian areas, and flooding promotes the germination and establishment of many native riparian plants.

NEPA Effects: Increased periodic flooding would not be expected to cause any adverse effect on nest sites because trees in which nest sites are situated already withstand floods, the increase in inundation frequency and duration is expected to remain within the range of tolerance of riparian trees, and nest sites are located above floodwaters. Therefore, increased duration of inundation from CM2 and CM5 would not result in an adverse effect on cormorants, herons and egrets.

CEQA Conclusion: Increased periodic flooding would not be expected to cause any adverse effect on nest sites because trees in which nest sites are situated already withstand floods, the increase in inundation frequency and duration is expected to remain within the range of tolerance of riparian trees, and nest sites are located above floodwaters. Therefore, increased duration of inundation from CM2 and CM5 would have a less-than-significant impact on cormorants, herons and egrets.

Short-Eared Owl and Northern Harrier

This section describes the effects of Alternative 1B, including water conveyance facilities construction and implementation of other conservation components, on short-eared owl and northern harrier. Modeled habitat for short-eared owl and northern harrier include tidal brackish and freshwater emergent wetland, nontidal freshwater perennial emergent wetland, managed wetland, other natural seasonal wetland, grassland, alkali seasonal wetland, vernal pool complex, and selected cultivated lands.

Construction and restoration associated with Alternative 1B conservation measures would result in both temporary and permanent losses of modeled habitat for short-eared owl and northern harrier as indicated in Table 12-1B-46. Full implementation of Alternative 1B would include the following conservation actions over the term of the BDCP which would also benefit short-eared owl and northern harrier (BDCP Chapter 3, Section 3.3, Biological Goals and Objectives).
• Restore or create at least 6,000 acres of tidal brackish emergent wetland in CZ 11 including at least 1,500 acres of middle and high marsh (Objectives TBEWNC1.1 and TBEWNC1.2, associated with CM4).

• Restore or create at least 24,000 acres of tidal freshwater emergent wetland in CZ 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.2, associated with CM4).

• Create at least 1,200 acres of nontidal marsh consisting of a mosaic of nontidal perennial aquatic and nontidal freshwater emergent wetland natural communities (Objective NFEW/NPANC1.1, associated with CM10).

• Protect at least 8,000 acres of grassland with at least 2,000 acres protected in CZ 1, at least 1,000 acres protected in CZ 8, at least 2,000 acres protected in CZ 11, and the remainder distributed among CZs 1, 2, 4, 5, 7, 8, and 11 (Objective GNC1.1, associated with CM3).

• Restore at least 2,000 acres of grasslands (Objective GNC1.2, associated with CM8).

• Protect at least 150 acres of alkali seasonal wetland and at least 600 acres of existing vernal pool complex in CZs 1, 8, and/or 11 (Objectives ASWNC1.1 and VPNC1.1, associated with CM3).

• Protect and enhance at least 8,100 acres of managed wetland, at least 1,500 acres of which are in the Grizzly Island Marsh Complex (Objective MWNC1.1, associated with CM3).

• Increase prey availability and accessibility for grassland-foraging species (Objectives ASWNC2.4, VPNC2.5, and GNC2.4, associated with CM11).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance habitat for these species and implementation of AMM1–AMM7, AMM27 Selenium Management and Mitigation Measures BIO-75 and BIO-121, impacts on short-eared owl and northern harrier would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

\(^{a}\) See Appendix 12E for detailed breakdown of conservation measure effects over the BDCP’s near-term and late long-term timeframes.

\(^{b}\) See discussion below for a description of applicable CMs.

\(^{c}\) LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

\(^{d}\) Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

**Impact BIO-121: Loss or Conversion of Habitat for and Direct Mortality of Short-Eared Owl and Northern Harrier**

Alternative 1B conservation measures would result in the combined permanent and temporary loss of up to 57,123 acres of modeled habitat for short-eared owl and northern harrier (50,269 acres of permanent loss and 6,854 acres of temporary loss, Table 12-1B-46). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass improvements (CM2), tidal habitat restoration (CM4), floodplain restoration (CM5), grassland restoration (CM8), vernal pool and wetland restoration (CM9), marsh restoration (CM10), and construction of conservation hatcheries (CM18). The majority of habitat loss would result from CM4. Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate short-eared owl and northern harrier modeled habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.

- **CM1 Water Facilities and Operation**: Construction of Alternative 1B conveyance facilities would result in the combined permanent and temporary loss of up to 2,785 acres of modeled short-eared owl and northern harrier habitat (2,012 acres of permanent loss, 773 acres of temporary loss). The majority of habitat removed would consist of grassland and alfalfa fields. Habitat losses would occur at various locations along the new canal route from the construction of the
canal and the associated borrow and spoil sites and at the intake sites along the Sacramento River. Permanent and temporary losses of foraging habitat would also occur at the new forebay site just south of Clifton Court Forebay and associated borrow and spoil sites. There are no occurrences of nesting short-eared owl and northern harrier that overlap with the construction footprint of CM1. However, northern harrier nests were detected throughout the central Delta during DHCCP surveys and there is suitable habitat throughout the study area for both species. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds would require preconstruction surveys and the establishment of no-disturbance buffers and would be available to address potential effects on short-eared owls and northern harriers if they were to nest in or adjacent to construction activities. The majority of habitat removed would be grassland and cultivated lands from proposed borrow and spoil sites adjacent to the canal alignment in CZs 4–8. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 1B construction locations.

- **CM2 Yolo Bypass Fisheries Enhancement**: Construction of the Yolo bypass fisheries enhancement would permanently remove 1,021 acres of modeled short-eared owl and northern harrier habitat in the Yolo Bypass in CZ 2. In addition, 471 acres of habitat would be temporarily removed. The impact would primarily consist of loss of acreages of pastures. The conversion is expected to occur during the first 10 years of Alternative 1B implementation.

- **CM4 Tidal Natural Communities Restoration**: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 39,017 acres of modeled short-eared owl and northern harrier habitat. The majority of the losses would be managed wetlands and cultivated lands in CZs 1, 2, 4, 5, 6, 7, 8, 10, and 11. Tidal restoration actions through CM4 would restore an estimated 55,000 acres of tidal natural communities. These restored wetland areas could provide suitable nesting habitat for short-eared owl and northern harrier. Consequently, although existing nesting habitat for short-eared owl and northern harrier would be removed, restoration of wetland habitats is expected to benefit marsh associated ground nesting birds by increasing the extent and value of their nesting habitat. Grizzley Island supports the only known resident population of short-eared owls in the Suisun Marsh and Sacramento-San Joaquin River Delta (Roberson 2008). Grizzley Island does not overlap with the hypothetical footprint for CM4. However, this is an important breeding area for short-eared owl and if restoration footprints were changed during the implementation process of BDCP to overlap with this area, the effects on breeding short-eared owls could likely be adverse. Future NEPA and CEQA analysis would be conducted for restoration projects under BDCP and if restoration was proposed to occur outside of the hypothetical footprints used for this programmatic analysis, potential impacts on these species would be captured in the project-level analysis (Appendix 3B, Section 3.2.5).

- **CM5 Seasonally Inundated Floodplain Restoration**: Construction of setback levees to restore seasonally inundated floodplain would permanently and temporarily remove approximately 2,086 acres of modeled short-eared owl and northern harrier habitat (1,332 permanent, 754 temporary). These losses would be expected to occur along the San Joaquin River and other major waterways in CZ 7.

- **CM7 Riparian Natural Community Restoration**: Riparian restoration would permanently remove approximately 623 acres of short-eared owl and northern harrier habitat as part of tidal restoration and 2,479 acres of habitat as part of seasonal floodplain restoration.

- **CM8 Grassland Natural Community Restoration**: Restoration of grassland is expected to be implemented on agricultural lands and would result in the conversion of 1,066 acres of
cultivated lands to grassland in CZs 1, 2, 4, 5, 7, 8, and 11. The resulting 2,000 acres of grassland would provide habitat for short-eared owl and northern harrier.

- **CM11 Natural Communities Enhancement and Management**: A variety of habitat management actions included in **CM11 Natural Communities Enhancement and Management** that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP.

Habitat management- and enhancement-related activities could short-eared owl and northern harrier nests. If either species were to nest in the vicinity of a worksite, equipment operation could destroy nests, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75, **Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds**, would be available to minimize these adverse effects.

- **CM18 Conservation Hatcheries**: Implementation of CM18 would remove up to 35 acres of short-eared owl and northern harrier habitat for the development of a delta and longfin smelt conservation hatchery in CZ 1. The loss is expected to occur during the first 10 years of Plan implementation.

- **Operations and Maintenance**: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect short-eared owl and northern harrier use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7, Mitigation Measure BIO-75, and conservation actions as described below.

- **Injury and Direct Mortality**: Construction-related activities would not be expected to result in direct mortality of adult or fledged short-eared owl and northern harrier if they were present in the Plan Area, because they would be expected to avoid contact with construction and other equipment. If either species were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to minimize these adverse effects.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

**Near-Term Timeframe**

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. The Plan would remove 21,951 acres of modeled habitat (15,850 permanent, 6,101 temporary) for short-eared owl and northern harrier in the study area.
area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 9,199 acres), and implementing other conservation measures (CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, CM5 Seasonally Inundated Floodplain Restoration, CM7, Riparian Natural Community Restoration, CM8 Grassland Natural Community Restoration, CM10 Nontidal Marsh Restoration, and CM18 Conservation Hatcheries—12,752 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 would be 1:1 for restoration/creation and 1:1 protection of habitat. Using these typical ratios would indicate that 9,199 acres of habitat should be restored and 9,199 acres should be protected to compensate for the CM1 losses of short-eared owl and northern harrier habitat. The near-term effects of other conservation actions would remove 12,752 acres of modeled habitat, and therefore require 12,752 acres of restoration and 12,752 acres of protection of short-eared owl and northern harrier habitat using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection).

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, protecting 4,800 acres of managed wetland natural community, protecting 15,400 acres of non-rice cultivated lands, protecting 900 acres of rice or rice equivalent habitat, and restoring 19,150 acres of tidal wetlands (Table 3-4 in Chapter 3). These conservation actions are associated with CM3, CM4, and CM8 and would occur in the same timeframe as the construction and early restoration losses.

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide nesting and foraging habitat for short-eared owl and northern harrier and reduce the effects of current levels of habitat fragmentation. Small mammal populations would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadways within protected cultivated lands (Objective SWHA2.2). Remnant patches of grassland or other uncultivated areas would also be protected and maintained as part of the cultivated lands reserve system which would provide additional foraging habitat and a source of rodent prey that could recolonize cultivated fields (Objective CLNC1.3). The protection of managed wetlands (including upland grassland components) would preserve habitat for short-eared owl and northern harrier (Objective MWNC1.1). Protection and enhancement of managed wetlands to meet this objective would focus on highly degraded areas in order to provide the greatest possible level of enhancement benefit to the managed wetland natural community and associated species. Managed wetland protection and enhancement would be concentrated in Suisun Marsh, which currently supports a high concentration of nesting short-eared owls on Grizzly Island.

The restoration of 19,150 acres of tidal natural communities, including transitional uplands would provide nesting and foraging habitat for short-eared owl and northern harrier. Short-eared owl and northern harrier nest in open habitats within cultivated lands including alfalfa, irrigated pasture, and other grain fields. At least 15,400 acres of cultivated lands that provide habitat for covered and other native wildlife species would be protected in the near-term time period (Objective CLNC1.1).
minimum of 87% of cultivated lands protected by the late long-term time period would be in alfalfa, irrigated pasture, and other hay crops (Objective SH1.2). This biological objective provides an estimate for the proportion of cultivated lands protected in the near-term time period which would provide suitable nesting and foraging habitat for short-eared owl and northern harrier.

The acres of protection contained in the near-term Plan goals satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1 and the effects from other near-term restoration actions. The acres of restoration in the near-term satisfy the project-level effects of CM1, but are 1,661 acres short of satisfying the compensation required for other near-term impacts. Mitigation Measure BIO-121, Compensate for Loss of Short-Eared Owl and Northern Harrier Nesting Habitat, would be available to address the adverse effect of near-term habitat loss.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spills, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.

The short-eared owl and the northern harrier are not covered species under the BDCP. For the BDCP to avoid adverse effects on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would be available to address this adverse effect.

**Late Long-Term Timeframe**

Based on modeled habitat, the study area supports approximately 406,784 acres of modeled nesting and foraging habitat for short-eared owl and northern harrier. Alternative 1B as a whole would result in the permanent loss of and temporary effects on 57,123 acres of modeled short-eared owl and northern harrier habitat during the term of the Plan (14% of the modeled habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures.

The Plan includes conservation commitments through CM3 Natural Communities Protection and Restoration, CM4 Tidal Natural Communities Restoration, and CM8 Grassland Natural Community Restoration, to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex, protect 8,100 acres of managed wetland, protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species, and restore at least 65,000 acres of tidal wetlands (Table 3-4 in Chapter 3).

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWN1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide nesting and foraging habitat for short-eared owl and northern harrier and reduce the effects of current levels of habitat fragmentation. Small mammal populations would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives
Alternative 1B
Terrestrial Biological Resources

ASWNC2.4, VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadways within protected cultivated lands (Objective SWHA2.2). Remnant patches of grassland or other uncultivated areas would also be protected and maintained as part of the cultivated lands reserve system which would provide additional foraging habitat and a source of rodent prey that could recolonize cultivated fields (Objective CLNC1.3). The protection of managed wetlands (including upland grassland components) would preserve habitat for short-eared owl and northern harrier (Objective MWNC1.1). Protection and enhancement of managed wetlands to meet this objective would focus on highly degraded areas in order to provide the greatest possible level of enhancement benefit to the managed wetland natural community and associated species. Managed wetland protection and enhancement would be concentrated in Suisun Marsh, which supports a high concentration of nesting short-eared owls on Grizzly Island. At least 1,500 acres of the managed wetlands would be protected and enhanced on Grizzly Island by the late long-term time period. The restoration of 19,150 acres of tidal natural communities, including transitional uplands would provide nesting and foraging habitat for short-eared owl and northern harrier. Short-eared owl and northern harrier nest in open habitats within cultivated lands including alfalfa, irrigated pasture, and other grain fields. A minimum of 87% of the 48,625 acres of cultivated lands protected by the late long-term time period (Objective CLNC1.1) would be managed in alfalfa, irrigated pasture, and other hay crops (Objective SH1.2) which are compatible crop types for these species.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures. Short-eared owl and northern harrier are not species that are covered under the BDCP, and preconstruction surveys for noncovered avian species would be required to ensure that active nests are detected and avoided. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would be available to address this adverse effect.

NEPA Effects: The loss of short-eared owl and northern harrier habitat and potential for direct mortality of these special-status species under Alternative 1B would represent an adverse effect in the absence of other conservation actions. However, with habitat protection and restoration associated with CM3, CM8, and CM11, guided by biological goals and objectives and by AMM1–AMM7, which would be in place throughout the construction period, the effects of habitat loss from Alternative 1B would not be adverse under NEPA. Short-eared owl and northern harrier are not covered species under the BDCP, and preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75 would be available to address the adverse effect of direct mortality on short-eared owl and northern harrier.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide
sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. The Plan would remove 21,951 acres of modeled habitat (15,850 permanent, 6,101 temporary) for short-eared owl and northern harrier in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 9,199 acres), and implementing other conservation measures (CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, CM5 Seasonally Inundated Floodplain Restoration, CM7, Riparian Natural Community Restoration, CM8 Grassland Natural Community Restoration, CM10 Nontidal Marsh Restoration, and CM18 Conservation Hatcheries—12,752 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 would be 1:1 for restoration/creation and 1:1 protection of habitat. Using these typical ratios would indicate that 9,199 acres of habitat should be restored and 9,199 acres should be protected to compensate for the CM1 losses of short-eared owl and northern harrier habitat. The near-term effects of other conservation actions would remove 12,752 acres of modeled habitat, and therefore require 12,752 acres of restoration and 12,752 acres of protection of short-eared owl and northern harrier habitat using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection).

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, protecting 4,800 acres of managed wetland natural community, protecting 15,400 acres of non-rice cultivated lands, protecting 900 acres of rice or rice equivalent habitat, and restoring 19,150 acres of tidal wetlands (Table 3-4 in Chapter 3). These conservation actions are associated with CM3, CM4, and CM8 and would occur in the same timeframe as the construction and early restoration losses.

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide nesting and foraging habitat for short-eared owl and northern harrier and reduce the effects of current levels of habitat fragmentation. Small mammal populations would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Remnant patches of grassland or other uncultivated areas would also be protected and maintained as part of the cultivated lands reserve system which would provide additional foraging habitat and a source of rodent prey that could recolonize cultivated fields (Objective CLNC1.3). The protection of managed wetlands (including upland grassland components) would preserve habitat for short-eared owl and northern harrier (Objective MWNC1.1). Protection and enhancement of managed wetlands to meet this objective would focus on highly degraded areas in order to provide the greatest possible level of enhancement benefit to the managed wetland natural community and associated species. Managed wetland protection and enhancement would be concentrated in Suisun Marsh, which supports a high concentration of nesting short-eared owls on Grizzly Island.

The restoration of 19,150 acres of tidal natural communities, including transitional uplands would provide nesting and foraging habitat for short-eared owl and northern harrier. Short-eared owl and
northern harrier nest in open habitats within cultivated lands including alfalfa, irrigated pasture, and other grain fields. At least 15,400 acres of cultivated lands that provide habitat for covered and other native wildlife species would be protected in the near-term time period (Objective CLNC1.1). A minimum of 87% of cultivated lands protected by the late long-term time period would be in alfalfa, irrigated pasture, and other hay crops (Objective SH1.2). This biological objective provides an estimate for the proportion of cultivated lands protected in the near-term time period which would provide suitable nesting and foraging habitat for short-eared owl and northern harrier. These biological goals and objectives would inform the near-term protection and restoration efforts and represent performance standards for considering the effectiveness of restoration actions.

The acres of protection contained in the near-term Plan goals satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1 and the effects from other near-term restoration actions. The acres of restoration in the near-term satisfy the project-level effects of CM1, but are 1,661 acres short of satisfying the compensation required for other near-term impacts. The implementation of Mitigation Measure BIO-121, Compensate for Loss of Short-Eared Owl and Northern Harrier Nesting Habitat, would reduce the impact of near-term habitat loss to a less-than-significant level.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.

The short-eared owl and the northern harrier are not covered species under the BDCP. For the BDCP to avoid adverse effects on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. The implementation of Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would reduce this potential impact to a less-than-significant level.

**Late Long-Term Timeframe**

Based on modeled habitat, the study area supports approximately 406,784 acres of modeled nesting and foraging habitat for short-eared owl and northern harrier. Alternative 1B as a whole would result in the permanent loss of and temporary effects on 57,123 acres of modeled short-eared owl and northern harrier habitat during the term of the Plan (14% of the modeled habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures.

The Plan includes conservation commitments through CM3 Natural Communities Protection and Restoration, CM4 Tidal Natural Communities Restoration, and CM8 Grassland Natural Community Restoration, to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex, protect 8,100 acres of managed wetland, protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species, and restore at least 65,000 acres of tidal wetlands (Table 3-4 in Chapter 3).
Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide nesting and foraging habitat for short-eared owl and northern harrier and reduce the effects of current levels of habitat fragmentation. Small mammal populations would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Remnant patches of grassland or other uncultivated areas would also be protected and maintained as part of the cultivated lands reserve system which would provide additional foraging habitat and a source of rodent prey that could recolonize cultivated fields (Objective CLNC1.3). The protection of managed wetlands (including upland grassland components) would preserve habitat for short-eared owl and northern harrier (Objective MWNC1.1). Protection and enhancement of managed wetlands to meet this objective would focus on highly degraded areas in order to provide the greatest possible level of enhancement benefit to the managed wetland natural community and associated species. Managed wetland protection and enhancement would be concentrated in Suisun Marsh, which supports a high concentration of nesting short-eared owls on Grizzly Island. At least 1,500 acres of the managed wetlands would be protected and enhanced on Grizzly Island by the late long-term time period. The restoration of 19,150 acres of tidal natural communities, including transitional uplands would provide nesting and foraging habitat for short-eared owl and northern harrier. Short-eared owl and northern harrier nest in open habitats within cultivated lands including alfalfa, irrigated pasture, and other grain fields. A minimum of 87% of the 48,625 acres of cultivated lands protected by the late long-term time period (Objective CLNC1.1) would be managed in alfalfa, irrigated pasture, and other hay crops (Objective SH1.2) which are compatible crop types for these species.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures. Short-eared owl and northern harrier are not species that are covered under the BDCP. For the BDCP to have a less-than-significant impact on individuals, preconstruction surveys for noncovered avian species would be required to ensure that active nests are detected and avoided. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would be reduce the impact to a less-than-significant level.

Considering Alternative 1B’s protection and restoration provisions, which would provide acreages of new high-value or enhanced habitat in amounts suitable to compensate for habitats lost to construction and restoration activities, and with the implementation of AMM1–AMM7 and Mitigation Measures BIO-75 and BIO-121, the loss of habitat or direct mortality through implementation of Alternative 1B would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of either species. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on short-eared owl and northern harrier.
Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Mitigation Measure BIO-121: Compensate for Loss of Short-Eared Owl and Northern Harrier Nesting Habitat

DWR will restore and protect sufficient acres of suitable nesting habitat for short-eared owl and northern harrier such that the total acres of habitat impacted in the near-term timeframe are mitigated at a ratio of 1:1. Restored habitat could consist of grassland or managed wetlands.

Impact BIO-122: Effects on Short-Eared Owl and Northern Harrier Associated with Electrical Transmission Facilities

New transmission lines would increase the risk that short-eared owl and northern harrier could be subject to power line strikes, which could result in injury or mortality of these species. Short-eared owl and northern harrier would be at low risk of bird strike mortality based on factors assessed in the bird strike vulnerability analysis (BDCP Attachment 5J.C, Analysis of Potential Bird Collisions at Proposed BDCP Transmission Lines). Factors analyzed include the height of the new transmission lines and the flight behavior of species. The existing network of transmission lines in the Plan Area currently poses the same small risk for these species, and any incremental risk associated with the new power line corridors would also be expected to be low. AMM20 Greater Sandhill Crane would further reduce any adverse effects.

NEPA Effects: New transmission lines would minimally increase the risk for short-eared owl and northern harrier power line strikes. With the implementation of AMM20 Greater Sandhill Crane, the potential effect of the construction of new transmission lines on short-eared owl and northern harrier would not be adverse.

CEQA Conclusion: New transmission lines would minimally increase the risk for short-eared owl and northern harrier power line strikes. AMM20 Greater Sandhill Crane would reduce the potential impact of the construction of new transmission lines on short-eared owl and northern harrier to a less-than-significant level.

Impact BIO-123: Indirect Effects of Plan Implementation on Short-Eared Owl and Northern Harrier

Indirect construction- and operation-related effects: Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect short-eared owl and northern harrier use of modeled habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane, Table 4), although there are no available data to determine the extent to which these noise levels could affect short-eared owl or northern harrier. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would be available to minimize adverse effects.
effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7, including AMM2 Construction Best Management Practices and Monitoring, would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to short-eared owl and northern harrier could also have a negative effect on these species. AMM1–AMM7 would ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

**Methylmercury Exposure:** Covered activities have the potential to exacerbate bioaccumulation of mercury in avian species, including short-eared owl and northern harrier. Marsh (tidal and nontidal) and floodplain restoration have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury (see BDCP Chapter 3, Conservation Strategy, for details of restoration). Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community and floodplain restoration could indirectly affect short-eared owl and northern harrier, via uptake in lower tropic levels (as described in the BDCP, Appendix 5.D, Contaminants).

In addition, the potential mobilization or creation of methylmercury within the Plan Area varies with site-specific conditions and would need to be assessed at the project level. CM12 Methylmercury Management contains provisions for project-specific Mercury Management Plans. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would be available to address the uncertainty of methylmercury levels in restored tidal marsh and potential impacts on short-eared owl and northern harrier.

**Selenium Exposure:** Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher levels of selenium levels than shorebirds that prey on aquatic
Terrestrial Biological Resources

...invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including short-eared owl and northern harrier. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, Conservation Strategy, for details of restoration). Changes in selenium concentrations were analyzed in Chapter 8, Water Quality, and it was determined that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4–CM5) would lead to adverse effects on short-eared owl and northern harrier.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on short-eared owl and northern harrier from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of AMM27 Selenium Management (BDCP Appendix 3.C, Avoidance and Minimization Measures) which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

**NEPA Effects:** Noise and visual disturbances from the construction of water conveyance facilities could reduce short-eared owl and northern harrier use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect short-eared owl and northern harrier use of the surrounding habitat. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would be available to address adverse effects on nesting individuals in addition to AMM1–AMM7. Tidal habitat restoration could result in increased exposure of short-eared owl and northern harrier. This effect would be addressed through the implementation of AMM27 Selenium Management, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

Tidal habitat restoration is unlikely to have an adverse effect on short-eared owl and northern harrier through increased exposure to methylmercury, as these species currently nest and forage in tidal marshes where elevated methylmercury levels exist. However, it is unknown what concentrations of methylmercury are harmful to the species and the potential for increased exposure varies substantially within the study area. Site-specific restoration plans in addition to monitoring and adaptive management, described in CM12 Methylmercury Management, would address the uncertainty of methylmercury levels in restored tidal marsh. The site-specific planning phase of marsh restoration would be the appropriate place to assess the potential for risk of...
methylmercury exposure for California least tern, once site specific sampling and other information could be developed.

**CEQA Conclusion:** Noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities would have a less-than-significant impact on short-eared owl and northern harrier with the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds* and AMM1–AMM7. Tidal habitat restoration is unlikely to have a significant impact on short-eared owl and northern harrier through increased exposure to methylmercury, as these species currently nest and forage in tidal marshes where elevated methylmercury levels exist. However, it is unknown what concentrations of methylmercury are harmful to these species. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would better inform potential impacts and address the uncertainty of methylmercury levels in restored tidal marsh in the study area. Tidal habitat restoration could result in increased exposure of short-eared owl and northern harrier. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Therefore, the indirect effects of Alternative 1B implementation would not have an adverse effect on short-eared owl and northern harrier.

**Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds**

See Mitigation Measure BIO-75 under Impact BIO-75.

**Impact BIO-124: Periodic Effects of Inundation on Short-Eared Owl and Northern Harrier as a Result of Implementation of Conservation Components**

Flooding of the Yolo Bypass from Fremont Weir operations (*CM2 Yolo Bypass Fisheries Enhancement*) would increase the frequency and duration of inundation on approximately 2,926–8,060 acres of modeled short-eared owl and northern harrier habitat (Table 12-1B-46).

Based on hypothetical footprints, implementation of *CM5 Seasonally Inundated Floodplain Restoration* could result in the periodic inundation of up to approximately 5,978 acres of modeled habitat (Table 12-1B-46), the majority of which would be pasture and other cultivated lands.

Reduced foraging habitat availability may be expected during the fledgling period of the nesting season due to periodic inundation. However, inundation would occur during the nonbreeding season and would not be expected to have an adverse effect on either species.

**NEPA Effects:** Periodic inundation of floodplains would not result in an adverse effect on short-eared owl and northern harrier because inundation is expected to occur prior to the breeding season.

**CEQA Conclusion:** Periodic inundation of floodplains would not have a significant impact on short-eared owl and northern harrier because inundation is expected to occur prior to the breeding season.
**Redhead and Tule Greater White-Fronted Goose**

Impacts, relevant protection and restoration actions, and mitigation requirements under CEQA are discussed for these species in the *General Terrestrial Biology Effects* section under Impacts BIO-178 through BIO-183. Further details of the methods of analysis for waterfowl and shorebirds can be found in the *BDCP Waterfowl and Shorebird Effects Analysis* (Ducks Unlimited 2013).

**Mountain Plover**

This section describes the effects of Alternative 1B, including water conveyance facilities construction and implementation of other conservation components, on mountain plover. Modeled habitat for mountain plover include grassland, alkali seasonal wetland, vernal pool complex, alfalfa, grain and hay, pasture, and idle cropland throughout the study area.

Construction and restoration associated with Alternative 1B conservation measures would result in both temporary and permanent losses of modeled habitat for mountain plover as indicated in Table 12-1B-47. Full implementation of Alternative 1B would include the following biological objectives over the term of the BDCP which would also benefit the mountain plover (*BDCP Chapter 3, Conservation Strategy*).

- Protect at least 8,000 acres of grassland with at least 2,000 acres protected in CZ 1, at least 1,000 acres protected in CZ 8, at least 2,000 acres protected in CZ 11, and the remainder distributed among CZs 1, 2, 4, 5, 7, 8, and 11 (Objective GNC1.1, associated with CM3).
- Restore at least 2,000 acres of grasslands (Objective GNC1.2, associated with CM8).
- Protect at least 150 acres of alkali seasonal wetland and at least 600 acres of existing vernal pool complex in CZs 1, 8, and/or 11 (Objectives ASWNC1.1 and VPNC1.1, associated with CM3).
- Increase prey availability and accessibility for grassland-foraging species (Objectives ASWNC2.4, VPNC2.5, GNC2.4, associated with CM11).
- Protect at least 48,625 acres of cultivated lands that provide suitable habitat for covered and other native wildlife species (Objective CLNC1.1, associated with CM3).
- Within the at least 48,625 acres of protected cultivated lands, protect at least 42,275 acres of cultivated lands as Swainson's hawk foraging habitat with at least 50% in very high-value habitat in CZs 2, 3, 4, 5, 7, 8, 9, and 11 (Objective SH1.2, associated with CM3).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance these natural communities for the species, impacts on mountain plover would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

\(^a\) See Appendix 12E for detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

\(^b\) See discussion below for a description of applicable CMs.

\(^c\) LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

\(^d\) Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-125: Loss orConversion of Habitat for and Direct Mortality of Mountain Plover

Alternative 1B conservation measures would result in the combined permanent and temporary loss of up to 34,581 acres of modeled habitat for mountain plover (29,160 acres of permanent loss and 5,421 of temporary loss, Table 12-1B-47). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass fisheries improvements (CM2), tidal habitat restoration (CM4), floodplain restoration (CM5), riparian restoration (CM7), grassland restoration (CM8), vernal pool and wetland restoration (CM9), nontidal marsh restoration (CM10), and construction of conservation hatcheries (CM18). The majority of habitat loss (20,880 acres) would result from CM4. Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, and the construction of recreational trails, signs, and facilities, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate mountain plover modeled wintering habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follows the individual conservation measure discussions.

- **CM1 Water Facilities and Operation:** Construction of Alternative 1B conveyance facilities would result in the combined permanent and temporary loss of up to 7,490 acres of modeled mountain plover wintering habitat (2,962 acres of permanent loss, 4,528 acres of temporary loss) from CZ 4, CZ 5, CZ 6, CZ 7 and CZ 8. The primary impact is from the construction of the canal and from the potential borrow and spoil areas on either side of the canal throughout the central Delta. The CM1 construction footprint does not overlap with any occurrences of mountain plover. However, the study area does overlap with the wintering range...
for the species and suitable habitat exists throughout the study area. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 1B construction locations.

- **CM2 Yolo Bypass Fisheries Enhancement**: Construction of the Yolo bypass fisheries enhancement would result in the combined permanent and temporary loss of up to 1,274 acres of modeled mountain plover wintering habitat (898 acres of permanent loss, 376 acres of temporary loss) in the Yolo Bypass in CZ 2. Impacted habitat would consist primarily of grassland and pasture. Most of the grassland losses would occur at the north end of the bypass below Fremont Weir, along the Toe Drain/Tule Canal, and along the west side channels. Realignment of Putah Creek could also involve excavation and grading in alkali seasonal wetland complex habitat as a new channel is constructed. The loss is expected to occur during the first 10 years of Alternative 1B implementation.

- **CM4 Tidal Natural Communities Restoration**: Tidal habitat restoration site preparation and inundation would permanently remove an estimated 20,880 acres of modeled mountain plover habitat. The majority of the acres lost would consist of cultivated lands in CZs 1, 2, 4, 5, 6, and/or 7. Grassland losses would likely occur in the vicinity of Cache Slough, on Decker Island in the West Delta ROA, on the up slope fringes of Suisun Marsh, and along narrow bands adjacent to waterways in the South Delta ROA. Tidal restoration would directly impact and fragment grassland just north of Rio Vista in and around French and Prospect Islands, and in an area south of Rio Vista around Threemile Slough. Losses of alkali seasonal wetland complex habitat would likely occur in the south end of the Yolo Bypass and on the northern fringes of Suisun Marsh.

- **CM5 Seasonally Inundated Floodplain Restoration**: Construction of setback levees to restore seasonally inundated floodplain would permanently and temporarily remove approximately 1,450 acres of modeled mountain plover habitat (933 permanent, 517 temporary). These losses would be expected after the first 10 years of Alternative 1B implementation along the San Joaquin River and other major waterways in CZ 7.

- **CM7 Riparian Natural Community Restoration**: Riparian restoration would permanently remove approximately 370 acres of mountain plover wintering habitat as part of tidal restoration and 1,489 acres of habitat as part of seasonal floodplain restoration.

- **CM8 Grassland Natural Community Restoration** and **CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration**: Temporary construction-related disturbance of grassland habitat would result from implementation of CM8 and CM9 in in CZs 1, 2, 4, 5, 7, 8, and 11. However, all areas would be restored after the construction periods. Grassland restoration would be implemented on agricultural lands that also provide wintering habitat for mountain plover and would result in the conversion of 837 acres of cultivated lands to grassland.

- **CM10 Nontidal Marsh Restoration**: Implementation of CM10 Nontidal Marsh Restoration would result in the permanent removal of 705 acres of mountain plover habitat.

- **CM11 Natural Communities Enhancement and Management**: A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of mountain plover habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available mountain plover habitat. CM11 would also include the construction of recreational-related facilities including trails, interpretive signs, and picnic
The construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible. However, approximately 50 acres of grassland habitat would be lost from the construction of trails and facilities.

- **CM18 Conservation Hatcheries**: Implementation of CM18 would remove up to 35 acres of modeled mountain plover habitat for the development of a delta and longfin smelt conservation hatchery in CZ 1.

- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect mountain plover use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7 and conservation actions as described below.

- Injury and Direct Mortality: Construction would not be expected to result in direct mortality of mountain plover because foraging individuals would be expected to temporarily avoid the increased noise and activity associated with construction areas.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

**Near-Term Timeframe**

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. The Plan would remove 13,316 acres (8,412 permanent, 4,904 temporary) of modeled mountain plover wintering habitat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 7,490 acres), and implementing other conservation measures (CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, CM7 Riparian Natural Community Restoration, CM8 Grassland Natural Community Restoration, CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration, CM11 Natural Communities Enhancement and Management and CM18 Conservation Hatcheries—5,826 acres).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 for protection of habitat. Using this ratio would indicate that 14,980 acres should be protected to compensate for the CM1 losses of 7,490 acres of mountain plover wintering habitat. The near-term effects of other conservation actions would remove 5,826 acres of modeled habitat, and therefore require 11,652 acres of protection of mountain plover habitat using the same typical NEPA and CEQA ratio (2:1 for protection).

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,400 acres of non-rice cultivated lands (Table 3-4 in Chapter 3). These conservation actions are associated with CM3, CM8, and CM9 and would occur in the same timeframe as the construction and early restoration losses thereby avoiding adverse effects of habitat loss on mountain plover wintering in the study area. Grassland restoration and
Alternative 1B
Terrestrial Biological Resources

Protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand mountain plover wintering habitat and reduce the effects of current levels of habitat fragmentation. Under CM11 Natural Communities Enhancement and Management, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential wintering habitat for mountain plover (Objective CLNC1.1). Approximately 87% of cultivated lands protected by the late long-term time period would be in alfalfa and pasture crop types (very high- and high-value crop types for Swainson’s hawk (Objective SH1.2) which are also modeled habitat for wintering mountain plover. This biological objective provides an estimate for the high proportion of cultivated lands protected in the near-term time period which would be suitable for mountain plover.

The combined acres of restoration and protection of 3,660 acres of grassland, vernal pool complex, and alkali seasonal wetland contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1. However, some portion of the 15,400 acres of cultivated lands protected in the near-term timeframe would need to include suitable crop types for these species in order to avoid an adverse effect of habitat loss from CM1. The conservation commitment is 7,572 acres short of meeting the compensation for other near-term effects on mountain plover habitat. Mitigation Measure BIO-125, Compensate for the Near-Term Loss of Mountain Plover Wintering Habitat, would be available to address the adverse effect of near-term high-value habitat loss by providing crop management requirements for CM1 compensation and requiring acreage compensation for the other near-term effects.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal andReuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.

Late Long-Term Timeframe

Based on the habitat model, the study area supports approximately 269,411 acres of potential habitat for mountain plover. Alternative 1B as a whole would result in the permanent loss of and temporary effects on 34,631 acres of modeled mountain plover wintering habitat during the term of the Plan (13% of the total habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through CM3 Natural Communities Protection and Restoration, CM8 Grassland Natural Community Restoration, and CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3). Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and
alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand habitat for mountain plover and reduce the effects of current levels of habitat fragmentation. Under CM11 Natural Communities Enhancement and Management, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential wintering habitat for mountain plover (Objective CLNC1.1). Approximately 42,275 acres of cultivated lands protected would be in alfalfa and pasture crop types (very high- and high-value crop types for Swainson’s hawk (Objective SH1.2) which would also provide potential wintering habitat for mountain plover. The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.

**NEPA Effects:** The loss of mountain plover habitat and potential for mortality of this special-status species under Alternative 1B would represent an adverse effect in the absence of other conservation actions. However, with habitat protection and restoration associated with CM3, CM8, CM9, and CM11, guided by biological goals and objectives and by AMM1–AMM7, which would be in place throughout the construction period, and with implementation of Mitigation Measure BIO-125, Compensate for the Near-Term Loss of Mountain Plover Wintering Habitat, the effects of habitat loss and potential for direct mortality on mountain plover under Alternative 1B would not be adverse.

**CEQA Conclusion:**

**Near-Term Timeframe**

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. The Plan would remove 13,316 acres (8,412 permanent, 4,904 temporary) of modeled mountain plover wintering habitat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 7,490 acres), and implementing other conservation measures (CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, CM7 Riparian Natural Community Restoration, CM8 Grassland Natural Community Restoration, CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration, CM11 Natural Communities Enhancement and Management and CM18 Conservation Hatcheries—5,826 acres).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 for protection of habitat. Using this ratio would indicate that 14,980 acres should be protected to compensate for the CM1 losses of 7,490 acres of mountain plover wintering habitat. The near-term effects of other conservation actions would remove 5,826 acres of modeled habitat, and therefore require 11,652 acres of protection of mountain plover habitat using the same typical NEPA and CEQA ratio (2:1 for protection).
The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of
grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of
alkali seasonal wetland complex, and protecting 15,400 acres of non-rice cultivated lands (Table 3-4
in Chapter 3). These conservation actions are associated with CM3, CM8, and CM9 and would occur
in the same timeframe as the construction and early restoration losses thereby avoiding significant
impacts of habitat loss on mountain plover. Grassland restoration and protection would occur in CZs
1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11
would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1
and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and
vernal pool natural communities which would expand wintering habitat for mountain plover and
reduce the effects of current levels of habitat fragmentation. Under CM11 Natural Communities
Enhancement and Management, insect prey populations would be increased on protected lands,
enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and
GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would
provide approximately 15,400 acres of potential wintering habitat for mountain plover (Objective
CLNC1.1). Approximately 87% of cultivated lands protected by the late long-term time period would
be in alfalfa and pasture crop types (very high- and high-value crop types for Swainson’s hawk
(Objective SH1.2) which would also provide potential habitat for mountain plover wintering in the
study area. This biological objective provides an estimate for the high proportion of cultivated lands
protected in the near-term time period which would provide habitat for mountain plover.

The combined acres of restoration and protection of 3,660 acres of grassland, vernal pool complex,
and alkali seasonal wetland contained in the near-term Plan goals and the additional detail in the
biological objectives satisfy the typical mitigation that would be applied to the project-level effects of
CM1. However, some portion of the 15,400 acres of cultivated lands protected in the near-term
timeframe would need to include suitable crop types for these species in order to avoid the
significant impact of habitat loss resulting from CM1. The conservation commitment is 7,572 acres
short of meeting the compensation for other near-term effects on mountain plover habitat.

Implementation of Mitigation Measure BIO-125, Compensate for the Near-Term Loss of Mountain
Plover Wintering Habitat, would reduce the impact of near-term habitat loss to a less-than-
significant level.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2
Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention
Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and
Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged
Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or
minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are
described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.

**Late Long-Term Timeframe**

Alternative 1B as a whole would result in the permanent loss of and temporary effects on 34,631
acres of mountain plover habitat during the term of the Plan (13% of the total habitat in the study
area). The locations of these losses are described above in the analyses of individual conservation
measures. The Plan includes conservation commitments through CM3 Natural Communities
Protection and Restoration, CM8 Grassland Natural Community Restoration, and CM9 Vernal Pool and
Alkali Seasonal Wetland Complex Restoration to protect 8,000 acres and restore 2,000 acres of
grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali
seasonal wetland complex and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3). Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand wintering habitat for mountain plover and reduce the effects of current levels of habitat fragmentation. Under CM11 Natural Communities Enhancement and Management, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential habitat for mountain plover (Objective CLNC1.1). Approximately 42,275 acres of cultivated lands protected would be in alfalfa and pasture crop types (very high- and high-value crop types for Swainson's hawk (Objective SH1.2) which would also provide habitat for mountain plover.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.

Considering Alternative 1B’s protection and restoration provisions, which would provide acreages of new high-value or enhanced habitat in amounts suitable to compensate for habitats lost to construction and restoration activities, and with the implementation of AMM1–AMM7 and Mitigation Measure BIO-125, Compensate for the Near-Term Loss of Mountain Plover Wintering Habitat, the loss of habitat or direct mortality through implementation of Alternative 1B4 would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of mountain plover. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on mountain plover.

**Mitigation Measure BIO-125: Compensate for the Near-Term Loss of Mountain Plover Wintering Habitat**

DWR will manage and protect sufficient acres of cultivated lands such as pasture, grain and hay crops, or alfalfa to provide habitat for mountain plover such that the total acres of high-value habitat impacted in the near-term timeframe are mitigated at a ratio of 2:1. Additional grassland protection, enhancement, and management may be substituted for the protection of high-value cultivated lands.

**Impact BIO-126: Effects on Mountain Plover Associated with Electrical Transmission Facilities**

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of mountain plover. Mountain plovers congregate in flocks during the winter and travel between grasslands and cultivated lands that provide foraging habitat for the species. This flocking behavior puts them at risk of collisions with powerlines. Existing transmission lines in the
study area currently pose this risk. Plovers are primarily visual foragers and therefore, the risk for collision would be reduced by AMM20 Greater Sandhill Crane, which would require the installation of bird flight diverters on new and selected existing transmission lines in the study area.

**NEPA Effects:** New transmission lines are not expected to have an adverse effect on mountain plover because mortality from powerline strikes would be minimized with the implementation of AMM20 Greater Sandhill Crane which would require the installation of bird flight diverters on new and selected existing transmission lines in the study area. The risk for bird-power line strikes is, therefore, not expected to have an adverse effect on mountain plover.

**CEQA Conclusion:** New transmission lines would have a less-than-significant impact on mountain plover because mortality from powerline strikes would be minimized with the implementation of AMM20 Greater Sandhill Crane which would require the installation of bird flight diverters on new and selected existing transmission lines in the study area.

**Impact BIO-127: Indirect Effects of Plan Implementation on Mountain Plover**

Construction- and subsequent maintenance-related noise and visual disturbances could disrupt foraging, and reduce the functions of suitable foraging habitat for mountain plover. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane, Table 4*), although there are no available data to determine the extent to which these noise levels could affect mountain plover. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7 would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to mountain plover grassland habitat could also have a negative effect on the species. However, AMM1–AMM7 would also ensure that measures would be in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

**NEPA Effects:** Indirect effects on mountain plover as a result of Alternative 1B implementation could have adverse effects on the species through the modification of habitat. With the implementation of AMM1–AMM7, indirect effects as a result of Alternative 1B implementation would not have an adverse effect on mountain plover.

**CEQA Conclusion:** Indirect effects on mountain plover as a result of Alternative 1B implementation could have a significant impact on the species from modification of habitat. With the implementation of AMM1–AMM7, indirect effects as a result of Alternative 1B implementation would have a less-than-significant impact on mountain plover.

**Impact BIO-128: Periodic Effects of Inundation on Mountain Plover as a Result of Implementation of Conservation Components**

Flooding of the Yolo Bypass from Fremont Weir operations (*CM2 Yolo Bypass Fisheries Enhancement*) would increase the frequency and duration of inundation on approximately 1,158–3,650 acres of modeled mountain plover wintering habitat (Table 12-1B-47). Based on hypothetical footprints, implementation of *CM5 Seasonally Inundated Floodplain Restoration*, could result in the
periodic inundation of up to approximately 3,823 acres of modeled mountain plover habitat (Table 12-1B-47).

**NEPA Effects:** Implementation of CM2 and CM5 would periodically inundate suitable mountain plover foraging habitat. However, effects of periodic inundation would not have an adverse effect on mountain plover because birds would be expected to move to adjacent foraging habitat.

**CEQA Conclusion:** Implementation of CM2 and CM5 would periodically inundate suitable mountain plover foraging habitat. However, effects of periodic inundation would have a less-than-significant impact on mountain plover because birds would be expected to move to adjacent foraging habitat.

**Black Tern**

This section describes the effects of Alternative 1B, including water conveyance facilities construction and implementation of other conservation components, on black tern. Modeled nesting habitat for black tern in the study area is currently limited to rice in CZ 2.

Construction and restoration associated with Alternative 1B conservation measures would result in both temporary and permanent losses of modeled habitat for black tern as indicated in Table 12-1B-48. Full implementation of Alternative 1B would include the following biological objectives over the term of the BDCP which would also benefit the black tern (BDCP Chapter 3, Conservation Strategy).

- **Protect 700 acres of cultivated lands, with at least 500 acres consisting of rice land, to expand upon and buffer newly restored/created nontidal perennial habitat in CZ 2, (Objective GGS2.3, associated with CM3).**
- **Protect up to 1,700 acres of rice land or equivalent habitat (e.g. perennial wetland) in the Yolo Bypass if this portion meets the criteria specified in CM3, Reserve Design Requirements by Species for giant garter snake. Any remaining acreage (from a total 2,740 acre commitment) will consist of rice land or equivalent-value habitat outside the Yolo Bypass in CZs 1, 2, 4, or 5 (Objective GGS3.1, associated with CM3).**

As explained below, with the restoration and protection of these amounts of habitat, in addition to management activities that would enhance this habitat for the species and implementation of AMM1–AMM7 and Mitigation Measure BIO-75, impacts on black tern would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

<sup>a</sup> See Appendix 12E for detailed breakdown of conservation measure effects over the BDCP’s near-term and late long-term timeframes.

<sup>b</sup> See discussion below for a description of applicable CMs.

<sup>c</sup> LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

<sup>d</sup> Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-129a: Loss or Conversion of Habitat for and Direct Mortality of Black Tern

Alternative 1B conservation measures would result in the permanent loss of up to 260 acres of modeled nesting habitat for black tern, consisting of rice in CZ 2 (Table 12-1B-48). Conservation measures that would result in these losses are grassland restoration (CM8) and nontidal marsh restoration (CM10). Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follows the individual conservation measure discussions.

- **CM8 Grassland Natural Community Restoration:** Restoration of grassland is expected to be implemented on agricultural lands and would result in the conversion of 52 acres of rice lands to grassland in CZ 2 by the late-long time period. An estimated 30 acres of impact would occur in the first 10 years.

- **CM10 Nontidal Marsh Restoration:** Implementation of CM10 would result in the permanent removal of 208 acres of black tern nesting habitat in in CZ 2. An estimated 46 acres would be removed in the first 10 years.

- **CM11 Natural Communities Enhancement and Management:** A variety of habitat management actions that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP. Habitat management- and enhancement-related activities could disturb nesting black terns if they were to nest in the vicinity of a worksite. Equipment operation could destroy nests, and noise and visual
disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. The potential for these activities to result in direct mortality of black tern would be minimized with the implementation of and Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds.

- Operations and Maintenance: Postconstruction operation and maintenance of the restoration infrastructure could result in ongoing but periodic disturbances that could affect black tern nesting adjacent to maintenance areas. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7, Mitigation Measure BIO-75, and conservation actions as described below.

- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged black tern individuals if they were present in the study area, because they would be expected to avoid contact with construction and other equipment. If black tern were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. These effects would be avoided and minimized with the implementation of Mitigation Measure BIO-75.

- Late season flooding in the Yolo Bypass could result in the loss of rice (nesting habitat for black tern) by precluding the preparation and planting of rice fields. The methods for estimating loss of rice in the bypass and results are provided in BDCP Appendix J, Attachment 5J.E, Estimation of BDCP Impact on Giant Garter Snake Summer Foraging Habitat in the Yolo Bypass. This analysis concludes that the estimated loss of rice could be up to 1,662 acres by the late long-term timeframe. This potential impact is further described under Impact BIO-129c below.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. There would be no impacts on black tern nesting habitat resulting from the construction of the water conveyance facilities (CM1). However, there would be a loss of 76 acres of modeled nesting habitat for black tern in the study area in the near-term. These effects would result from implementing CM8 Grassland Natural Community Restoration and CM10 Nontidal Marsh Restoration.

The typical NEPA and CEQA project-level mitigation ratio would be 1:1 protection for the loss of cultivated lands including rice. Using this ratio would indicate that 76 acres of rice lands should be protected in CZ 2 to compensate for the losses of black tern nesting habitat.

The BDCP has committed to near-term goals of protecting 200 acres of rice and 700 acres of rice or equivalent habitat (Table 3-4 in Chapter 3). These conservation actions are associated with CM3 and would occur in the same timeframe as the early restoration losses. The BDCP also contains objectives for the giant garter snake to protect at least 500 acres of rice in CZ 2 and to protect up to 1,700 acres of rice land or equivalent habitat in the Yolo Bypass (if this portion meets the criteria
specified in CM3, *Reserve Design Requirements by Species* for giant garter snake, Objectives GGS2.3 and GGS 3.1) by the late long-term time period. These objectives would inform the near-term protection actions, and therefore some portion of the 200 acres of rice and 700 acres of rice or equivalent habitat would be expected to be restored in CZ 2. However, there is no near-term acreage commitment in the plan that is specific to CZ 2. In order to avoid an adverse effect on black tern from habitat loss, protection of 76 acres of rice would need to occur in CZ 2 in the near-term timeframe. Mitigation Measure BIO-129a, *Compensate for Loss of Black Tern Nesting Habitat*, would be available to address this adverse effect.

The Plan also includes commitments to implement AMM1 *Worker Awareness Training*, AMM2 *Construction Best Management Practices and Monitoring*, AMM3 *Stormwater Pollution Prevention Plan*, AMM4 *Erosion and Sediment Control Plan*, AMM5 *Spill Prevention, Containment, and Countermeasure Plan*, AMM6 *Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and AMM7 *Barge Operations Plan*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*. Black tern is not a covered species under the BDCP and in order to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

**Late Long-Term Timeframe**

Alternative 1B as a whole would result in the permanent loss of 260 acres of modeled black tern nesting habitat during the term of the Plan. This impact would result from the removal of rice in CZ 2. The Plan includes conservation commitments through CM3 *Natural Communities Protection and Restoration* to protect 500 acres of rice lands (Table 3-4 in Chapter 3) and up to 1,700 acres of rice lands or equivalent habitat for the giant garter snake (Objective GGS3.1) in CZ 2. The nesting habitat for black tern in the northern part of the study area has largely been reduced to rice lands, and these acres would provide protected nesting habitat for the species.

The Plan also includes commitments to implement AMM1 *Worker Awareness Training*, AMM2 *Construction Best Management Practices and Monitoring*, AMM3 *Stormwater Pollution Prevention Plan*, AMM4 *Erosion and Sediment Control Plan*, AMM5 *Spill Prevention, Containment, and Countermeasure Plan*, AMM6 *Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and CM7 *Barge Operations Plan*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*. Black tern is not a covered species under the BDCP and in order to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

**NEPA Effects:** The loss of black tern nesting habitat and potential for mortality of this special-status species under Alternative 1B would represent an adverse effect in the absence of other conservation actions. With habitat protection associated with CM3, guided by biological goals and objectives and by AMM1–AMM7, which would be in place throughout the construction period, the effects of habitat loss under Alternative 1B would not be adverse under NEPA. Black tern is not a covered species under the BDCP and the potential for mortality would be adverse without preconstruction surveys to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction*
Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would be available to address this adverse effect.

CEQA Conclusion:

Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. There would be no impacts on black tern nesting habitat resulting from the construction of the water conveyance facilities (CM1). However, there would be a loss of 76 acres of modeled nesting habitat for black tern in the study area in the near-term. These effects would result from implementing CM8 Grassland Natural Community Restoration and CM10 Nontidal Marsh Restoration.

The typical NEPA and CEQA project-level mitigation ratio would be 1:1 protection for the loss of cultivated lands including rice. Using this ratio would indicate that 76 acres of rice lands should be protected in CZ 2 to mitigate the losses of black tern nesting habitat.

The BDCP has committed to near-term goals of protecting 200 acres of rice and 700 acres of rice or equivalent habitat (Table 3-4 in Chapter 3). These conservation actions are associated with CM3 and would occur in the same timeframe as the early restoration losses. The BDCP also contains objectives for the giant garter snake to protect at least 500 acres of rice in CZ 2 and to protect up to 1,700 acres of rice land or equivalent habitat in the Yolo Bypass (if this portion meets the criteria specified in CM3, Reserve Design Requirements by Species for giant garter snake, Objectives GGS2.3 and GGS 3.1) by the late long-term time period. These objectives would inform the nearterm protection actions, and therefore some portion of the 200 acres of rice and 700 acres of rice or equivalent habitat would be expected to be restored in CZ 2. However, there is no near-term acreage commitment in the plan that is specific to CZ 2. Mitigation Measure BIO-129a, Compensate for Loss of Black Tern Nesting Habitat, which would require 1:1 protection of habitat in CZ 2 in the near-term timeframe, would reduce this potential impact to a less-than-significant level.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures. Black tern is not a covered species under the BDCP and in order to have a less-than-significant impact on individuals, preconstruction would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would reduce the potential impact on nesting black tern to a less-than-significant level.

Late Long-Term Timeframe

Alternative 1B as a whole would result in the permanent loss of 260 acres of modeled black tern nesting habitat during the term of the Plan. This impact would result from the removal of rice in CZ 2. The Plan includes conservation commitments through CM3 Natural Communities Protection and
Alternative 1B
Terrestrial Biological Resources

Restoration to protect 500 acres of rice lands (Table 3-4 in Chapter 3) and up to 1,700 acres of rice lands or equivalent habitat for the giant garter snake (Objective GGS3.1) in CZ 2.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, and AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures. Black tern is not a covered species under the BDCP and in order to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided.

Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, reduce the potential impact on nesting black tern to a less-than-significant level.

Considering these protection provisions, which would provide acreages of new or enhanced habitat in amounts greater than necessary to compensate for habitats lost to construction and restoration activities, loss of habitat or direct mortality through implementation of Alternative 1B would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the alternative would have a less-than-significant impact on black tern.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Mitigation Measure BIO-129a: Compensate for Loss of Black Tern Nesting Habitat

Because there is no near-term acreage commitment associated with the protection of rice in CZ 2, BDCP proponents must protect rice at a 1:1 ratio for each acre of rice impacted in CZ 2.

Impact BIO-129b: Indirect Effects of Plan Implementation on Black Tern

Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5J, Attachment 5J.D, Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane, Table 4), although there are no available data to determine the extent to which these noise levels could affect black tern. If black terns were to nest in or adjacent to work areas, construction and subsequent maintenance-related noise and visual disturbances could mask calls, disrupt foraging and nesting behaviors, and reduce the functions of suitable nesting habitat for these species. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would avoid the potential for adverse effects of construction-related activities on survival and productivity of nesting black terns. The use of mechanical equipment during restoration activities could cause the accidental release of petroleum or other contaminants that could affect black terns in the surrounding habitat. The inadvertent discharge of sediment or excessive dust adjacent to suitable habitat could also have an adverse effect on these species. AMM1–AMM7, including AMM2 Construction Best Management Practices and Monitoring, would minimize the likelihood of such spills and ensure that measures are in place to prevent runoff from the construction area and negative effects of dust on active nests.
Selenium Exposure: Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher levels of selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including black tern. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, Conservation Strategy, for details of restoration). Changes in selenium concentrations were analyzed in Chapter 8, Water Quality, and it was determined that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4–CM5) would lead to adverse effects on black tern.

Because of the uncertainty that exists at this programmatic level of review, there could be an effect on black tern from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of AMM27 Selenium Management (BDCP Appendix 3.C, Avoidance and Minimization Measures) which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

NEPA Effects: Noise and visual disturbances from the construction of conservation components could black tern use of modeled habitat adjacent to work areas. Moreover, the use of mechanical equipment for the construction of conservation components could cause the accidental release of petroleum or other contaminants, or the inadvertent discharge of sediment or excess dust adjacent
Alternative 1B
Terrestrial Biological Resources

to suitable habitat. AMM1–AMM7, and Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address adverse effects on nesting individuals. Tidal habitat restoration could result in increased exposure of black tern to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

**CEQA Conclusion:** Noise and visual disturbances from the construction of conservation components could black tern use of modeled habitat adjacent to work areas. Moreover, the use of mechanical equipment for the construction of conservation components could cause the accidental release of petroleum or other contaminants, or the inadvertent discharge of sediment or excess dust adjacent to suitable habitat. AMM1–AMM7, and Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce these impacts on a less-than-significant level. Tidal habitat restoration could result in increased exposure of black tern to selenium. This effect would be addressed through the implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats.

**Impact BIO-129c: Periodic Effects of Inundation on Black Tern Nesting Habitat as a Result of Implementation of Conservation Components**

Flooding of the Yolo Bypass would inundate 791–1,582 acres of suitable black tern nesting habitat (land currently managed as rice in CZ 2). Inundation would occur during the nonbreeding season but could reduce the availability of nesting habitat during years that flooding extends into the nesting season (past March). Extended inundation of the Yolo Bypass would not be expected to affect black tern nesting habitat. However, if periodic inundation took land out of rice production, this could have an adverse effect on black tern nesting habitat. Late season flooding in the Yolo Bypass could result in the loss of rice (nesting habitat for black tern) by precluding the preparation and planting of rice fields. The methods for estimating loss of rice in the bypass and results are provided in BDCP Appendix J, Attachment 5J.E, *Estimation of BDCP Impact on Giant Garter Snake Summer Foraging Habitat in the Yolo Bypass*. This analysis concludes that the estimated loss of rice could be up to 1,662 acres by the late long-term timeframe. The BDCP has committed to protect, restore and/or create up to 1,700 acres of rice in the Yolo Bypass (Objective GGS3.1). These acres of rice would be protected in areas that are less susceptible to inundation, which would benefit the black tern during years in which the magnitude and duration of inundation were increased.

**NEPA Effects:** Flooding of the Yolo Bypass is not expected to adversely affect nesting habitat for black tern. However, if flooding were to extend into the nesting season or were to significantly reduce rice production, it could also reduce suitable black tern nesting habitat. This potential effect would not be adverse with the creation and/or protection of 1,700 acres of rice in CZ 2 under BDCP Objective GGS3.1.

**CEQA Conclusion:** Flooding of the Yolo Bypass is not expected to have a significant impact on nesting habitat for black tern. However, if flooding were to significantly reduce rice production and reduce suitable black tern nesting habitat, this impact would be reduced to a less-than-significant level by the creation and/or protection of 1,700 acres of rice in CZ 2 under BDCP Objective GGS3.1.
California Horned Lark and Grasshopper Sparrow

This section describes the effects of Alternative 1B, including water conveyance facilities construction and implementation of other conservation components, on California horned lark and grasshopper sparrow. The primary impact of concern for grasshopper sparrow and California horned lark would be the loss of nest habitat in the Plan Area, which includes grassland, vernal pool complex, and alkali seasonal wetland natural communities and selected cultivated lands including grain and hay crops and pasture.

Construction and restoration associated with Alternative 1B conservation measures would result in both temporary and permanent losses of modeled breeding habitat for California horned lark and grasshopper sparrow as indicated in Table 12-1B-49. Full implementation of Alternative 1B would include the following biological objectives over the term of the BDCP which would also benefit the California horned lark and the grasshopper sparrow (BDCP Chapter 3, Conservation Strategy).

- Protect at least 8,000 acres of grassland with at least 2,000 acres protected in CZ 1, at least 1,000 acres protected in CZ 8, at least 2,000 acres protected in CZ 11, and the remainder distributed among CZs 1, 2, 4, 5, 7, 8, and 11 (Objective GNC1.1, associated with CM3).
- Restore at least 2,000 acres of grasslands (Objective GNC1.2, associated with CM8).
- Protect at least 150 acres of alkali seasonal wetland and at least 600 acres of existing vernal pool complex in CZs 1, 8, and/or 11 (Objectives ASWNC1.1 and VPNC1.1, associated with CM3).
- Protect at least 48,625 acres of cultivated lands that provide suitable habitat for covered and other native wildlife species (Objective CLNC1.1, associated with CM3).
- Within the at least 48,625 acres of protected cultivated lands, protect at least 42,275 acres of cultivated lands as Swainson’s hawk foraging habitat with at least 50% in very high-value habitat in CZs 2, 3, 4, 5, 7, 8, 9, and 11 (Objective SH1.2, associated with CM3).
- Increase prey availability and accessibility for grassland-foraging species (Objectives ASWNC2.4, VPNC2.5, and GNC2.4, associated with CM11).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance habitat for these species and implementation of AMM1–AMM7 and Mitigation Measure BIO-75, impacts on California horned lark and grasshopper sparrow would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.
Table 12-1B-49. Changes in California Horned Lark and Grasshopper Sparrow Modeled Habitat Associated with Alternative 1B (acres)

a See Appendix 12E for detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.
b See discussion below for a description of applicable CMs.
c LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.
d Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

Impact BIO-130: Loss or Conversion of Habitat for and Direct Mortality of California Horned Lark and Grasshopper Sparrow

Alternative 1B conservation measures would result in the combined permanent and temporary loss of up to 34,581 acres of modeled breeding habitat for California horned lark and grasshopper sparrow (29,160 acres of permanent loss and 5,421 acres of temporary loss; Table 12-1B-49). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass fisheries improvements (CM2), tidal habitat restoration (CM4), floodplain restoration (CM5), riparian restoration (CM7), grassland restoration (CM8), vernal pool and wetland restoration (CM9), nontidal marsh restoration (CM10), and construction of conservation hatcheries (CM18). The majority of habitat loss (20,880 acres) would result from CM4. Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, and the construction of recreational trails, signs, and facilities, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate California horned lark and grasshopper sparrow modeled habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.

- **CM1 Water Facilities and Operation**: Construction of Alternative 1B conveyance facilities would result in the combined permanent and temporary loss of up to 7,490 acres of modeled California horned lark and grasshopper sparrow habitat (2,962 acres of permanent loss, 4,528 acres of temporary loss) in CZ 4, CZ 5, CZ 6, CZ 7, and CZ 8. Habitat losses would occur at various locations along the new canal route from the construction of the canal and the associated
borrow and spoil sites and at the intake sites along the Sacramento River. Permanent and temporary losses of foraging habitat would also occur at the new forebay site just south of Clifton Court Forebay and associated borrow and spoil sites. Approximately 685 acres of impact would be from the new forebay constructed south of the Clifton Court Forebay in CZ 8.

Grasshopper sparrows were detected in DHCCP surveys south of Byron Highway in CZ 8 (1 occurrence) and east of Intakes 2 and 3 (6 occurrences), in the Stone Lakes NWR. However, the CM1 footprint does not overlap with any grasshopper sparrow or California horned lark occurrences. However, Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would require preconstruction surveys and the establishment of no-disturbance buffers and would be available to address potential effects on California horned larks and grasshopper sparrows if they were to nest in or adjacent to construction areas. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 1B construction locations.

- **CM2 Yolo Bypass Fisheries Enhancement:** Construction of the Yolo bypass fisheries enhancement would result in the combined permanent and temporary loss of up to 1,274 acres of modeled California horned lark and grasshopper sparrow habitat (898 acres of permanent loss, 376 acres of temporary loss) in the Yolo Bypass in CZ 2. Impacted habitat would consist primarily of grassland and pasture. Most of the grassland losses would occur at the north end of the bypass below Fremont Weir, along the Toe Drain/Tule Canal, and along the west side channels. Realignment of Putah Creek could also involve excavation and grading in alkali seasonal wetland complex habitat as a new channel is constructed. The loss is expected to occur during the first 10 years of Alternative 1B implementation.

- **CM4 Tidal Natural Communities Restoration:** Tidal habitat restoration site preparation and inundation would permanently remove an estimated 20,880 acres of modeled California horned lark and grasshopper sparrow habitat. The majority of the acres lost would consist of cultivated lands in CZs 1, 2, 4, 5, 6, and/or 7. Grassland losses would likely occur in the vicinity of Cache Slough, on Decker Island in the West Delta ROA, on the upslope fringes of Suisun Marsh, and along narrow bands adjacent to waterways in the South Delta ROA. Tidal restoration would directly impact and fragment grassland just north of Rio Vista in and around French and Prospect Islands, and in an area south of Rio Vista around Threemile Slough. Losses of alkali seasonal wetland complex habitat would likely occur in the south end of the Yolo Bypass and on the northern fringes of Suisun Marsh.

- **CM5 Seasonally Inundated Floodplain Restoration:** Construction of setback levees to restore seasonally inundated floodplain would permanently and temporarily remove approximately 1,450 acres of modeled California horned lark and grasshopper sparrow nesting habitat (933 permanent, 517 temporary). These losses would be expected after the first 10 years of Alternative 1B implementation along the San Joaquin River and other major waterways in CZ 7.

- **CM7 Riparian Natural Community Restoration:** Riparian restoration would permanently remove approximately 370 acres of California horned lark and grasshopper sparrow nesting habitat as part of tidal restoration and 1,489 acres as part of seasonal floodplain restoration.

- **CM8 Grassland Natural Community Restoration and CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration:** Temporary construction-related disturbance of grassland habitat would result from implementation of CM8 and CM9 in in CZs 1, 2, 4, 5, 7, 8, and 11. However, all areas would be restored after the construction periods. Grassland restoration would be implemented on agricultural lands that also provide nesting habitat for California horned lark and...
Alternative 1B
Terrestrial Biological Resources

Grasshopper sparrow and would result in the conversion of 837 acres of cultivated lands to grassland.

- **CM10 Nontidal Marsh Restoration:** Implementation of CM10 Nontidal Marsh Restoration would result in the permanent removal of 705 acres of California horned lark and grasshopper sparrow nesting habitat.

- **CM11 Natural Communities Enhancement and Management:** A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP. CM11 would also include the construction of recreational-related facilities including trails, interpretive signs, and picnic tables (BDCP Chapter 4, Covered Activities and Associated Federal Actions). The construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible. However, approximately 50 acres of grassland habitat would be lost from the construction of trails and facilities.

Habitat management- and enhancement-related activities could disturb California horned lark and grasshopper sparrow nests. If either species were to nest in the vicinity of a worksite, equipment operation could destroy nests, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would be available to address these adverse effects.

- **CM18 Conservation Hatcheries:** Implementation of CM18 would remove up to 35 acres of modeled California horned lark and grasshopper sparrow habitat for the development of a delta and longfin smelt conservation hatchery in CZ 1.

- **Operations and Maintenance:** Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect California horned lark and grasshopper sparrow use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7, Mitigation Measure BIO-75, and conservation actions as described below.

- **Injury and Direct Mortality:** Construction-related activities would not be expected to result in direct mortality of adult or fledged California horned lark and grasshopper sparrow if they were present in the Plan Area, because they would be expected to avoid contact with construction and other equipment. If either species were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to address these adverse effects.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.
Near-Term Timeframe

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. The Plan would remove 13,316 acres (8,412 permanent, 4,904 temporary) of modeled breeding habitat for California horned lark and grasshopper sparrow in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 7,490 acres), and implementing other conservation measures (CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, CM7 Riparian Natural Community Restoration, CM8 Grassland Natural Community Restoration, CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration, CM11 Natural Communities Enhancement and Management and CM18 Conservation Hatcheries—5,826 acres).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 for protection of habitat. Using this ratio would indicate that 14,980 acres should be protected to compensate for the CM1 losses of 7,490 acres of California horned lark and grasshopper sparrow habitat. The near-term effects of other conservation actions would remove 5,826 acres of modeled habitat, and therefore require 11,652 acres of protection of California horned lark and grasshopper sparrow nesting habitat using the same typical NEPA and CEQA ratio (2:1 for protection).

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,400 acres of non-rice cultivated lands (Table 3-4 in Chapter 3). These conservation actions are associated with CM3, CM8, and CM9 and would occur in the same timeframe as the construction and early restoration losses thereby avoiding adverse effects of habitat loss on California horned lark and grasshopper sparrow. Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand breeding habitat for California horned lark and grasshopper sparrow and reduce the effects of current levels of habitat fragmentation. Under CM11 Natural Communities Enhancement and Management, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4,VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential nesting habitat for California horned lark and grasshopper sparrow (Objective CLNC1.1). Approximately 87% of cultivated lands protected by the late long-term time period would be in alfalfa and pasture crop types (very high- and high-value crop types for Swainson's hawk (Objective SH1.2) which would also provide potential nesting habitat for California horned lark and grasshopper sparrow. This biological objective provides an estimate for the high proportion of cultivated lands protected in the near-term time period which would provide nesting habitat for California horned lark and grasshopper sparrow.

The combined acres of restoration and protection of 3,660 acres of grassland, vernal pool complex, and alkali seasonal wetland contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1. However, some portion of the 15,400 acres of cultivated lands protected in the near-term
Alternative 1B
Terrestrial Biological Resources

timeframe would need to include suitable crop types for these species in order to avoid an adverse effect of habitat loss from CM1. The conservation commitment is 7,572 acres short of meeting the compensation for other near-term effects on California horned lark and grasshopper sparrow habitat. Mitigation Measure BIO-130, Compensate for the Near-Term Loss of California Horned Lark and Grasshopper Sparrow Habitat, would be available to address the adverse effect of near-term high-value habitat loss by providing crop management requirements for CM1 compensation and requiring additional acreage compensation for the other near-term effects.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.

California horned lark and grasshopper sparrow are not covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would be available to address this adverse effect.

Late Long-Term Timeframe

Based on the habitat model, the study area supports approximately 269,411 acres of potential habitat for California horned lark and grasshopper sparrow. Alternative 1B as a whole would result in the permanent loss of and temporary effects on 34,631 acres of modeled California horned lark and grasshopper sparrow habitat during the term of the Plan (13% of the total habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through CM3 Natural Communities Protection and Restoration, CM8 Grassland Natural Community Restoration, and CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3). Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand breeding habitat for California horned lark and grasshopper sparrow and reduce the effects of current levels of habitat fragmentation. Under CM11 Natural Communities Enhancement and Management, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential nesting habitat for California horned lark and grasshopper sparrow (Objective CLNC1.1). Approximately 42,275 acres of cultivated lands protected would be in alfalfa and pasture crop types. These are very high- and high-value crop types for Swainson's hawk (Objective SH1.2) and would provide potential nesting habitat for California horned lark and grasshopper sparrow.
The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures. California horned lark and grasshopper sparrow are not covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would be available to address this adverse effect.

**NEPA Effects:** The loss of California horned lark and grasshopper sparrow habitat and potential for mortality of these special-status species under Alternative 1B would represent an adverse effect in the absence of other conservation actions. However, with habitat protection and restoration associated with CM3, CM8, CM9, and CM11, guided by biological goals and objectives and by AMM1–AMM7, which would be in place throughout the construction period, and with implementation of Mitigation Measure BIO-130, Compensate for the Near-Term Loss of California Horned Lark and Grasshopper Sparrow Habitat, the effects of habitat loss under Alternative 1B on California horned lark and grasshopper sparrow would not be adverse. California horned lark and grasshopper sparrow are not covered species under the BDCP and the potential for mortality would be an adverse effect without preconstruction surveys to ensure that nests are detected and avoided. Mitigation Measure BIO-75 would be available to address this effect.

**CEQA Conclusion:**

**Near-Term Timeframe**

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. The Plan would remove 13,316 acres (8,412 permanent, 4,904 temporary) of modeled breeding habitat for California horned lark and grasshopper sparrow in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 7,490 acres), and implementing other conservation measures (CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, CM7 Riparian Natural Community Restoration, CM8 Grassland Natural Community Restoration, CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration, CM11 Natural Communities Enhancement and Management and CM18 Conservation Hatcheries—5,826 acres).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 for protection of habitat. Using this ratio would indicate that 14,980 acres should be protected to compensate for the CM1 losses of 7,490 acres of California horned lark and grasshopper sparrow habitat. The near-term effects of other conservation actions would remove 5,826 acres of modeled habitat, and therefore require 11,652 acres of protection of California horned lark and grasshopper sparrow nesting habitat using the same typical NEPA and CEQA ratio (2:1 for protection).
The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,400 acres of non-rice cultivated lands (Table 3-4 in Chapter 3). These conservation actions are associated with CM3, CM8, and CM9 and would occur in the same timeframe as the construction and early restoration losses thereby avoiding significant impacts on California horned lark and grasshopper sparrow. Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand breeding habitat for California horned lark and grasshopper sparrow and reduce the effects of current levels of habitat fragmentation. Under CM11 Natural Communities Enhancement and Management, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential nesting habitat for California horned lark and grasshopper sparrow (Objective CLNC1.1).

Approximately 87% of cultivated lands protected by the late long-term time period would be in alfalfa and pasture crop types (very high- and high-value crop types for Swainson’s hawk (Objective SH1.2) which would also provide potential nesting habitat for California horned lark and grasshopper sparrow. This biological objective provides an estimate for the high proportion of cultivated lands protected in the near-term time period which would provide nesting habitat for California horned lark and grasshopper sparrow.

The combined acres of restoration and protection of 3,660 acres of grassland, vernal pool complex, and alkali seasonal wetland contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1. However, some portion of the 15,400 acres of cultivated lands protected in the near-term timeframe would need to include suitable crop types for these species in order to avoid the significant impact of habitat loss resulting from CM1. The conservation commitment is 7,572 acres short of meeting the compensation for other near-term effects on California horned lark and grasshopper sparrow habitat. Implementation of Mitigation Measure BIO-130, Compensate for the Near-Term Loss of California Horned Lark and Grasshopper Sparrow Habitat, would reduce the impact of near-term high-value habitat loss by providing crop management requirements for CM1 compensation and requiring additional acreage compensation for the other near-term effects.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.

California horned lark and grasshopper sparrow are not covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would reduce this potential impact to a less-than-significant level.
**Late Long-Term Timeframe**

Alternative 1B as a whole would result in the permanent loss of and temporary effects on 34,631 acres of California horned lark and grasshopper sparrow habitat during the term of the Plan (13% of the total habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures. The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through CM3 Natural Communities Protection and Restoration, CM8 Grassland Natural Community Restoration, and CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3). Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand breeding habitat for California horned lark and grasshopper sparrow and reduce the effects of current levels of habitat fragmentation. Under CM11 Natural Communities Enhancement and Management, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential nesting habitat for California horned lark and grasshopper sparrow (Objective CLNC1.1). Approximately 42,275 acres of cultivated lands protected would be in alfalfa and pasture crop types (very high- and high-value crop types for Swainson’s hawk (Objective SH1.2) which would also provide potential nesting habitat for California horned lark and grasshopper sparrow. The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures. California horned lark and grasshopper sparrow are not covered species under the BDCP. For the BDCP to avoid significant impacts on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would reduce this potential impact to a less-than-significant level.

Considering Alternative 1B’s protection and restoration provisions, which would provide acreages of new high-value or enhanced habitat in amounts suitable to compensate for habitats lost to construction and restoration activities, and with the implementation of AMM1–AMM7, Mitigation Measure BIO-75, and Mitigation Measure BIO-130, Compensate for the Near-Term Loss of California Horned Lark and Grasshopper Sparrow Habitat, the loss of habitat or direct mortality through implementation of Alternative 1B would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of either species. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on California horned lark and grasshopper sparrow.
Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Measure BIO-130: Compensate for the Near-Term Loss of California Horned Lark and Grasshopper Sparrow Habitat

DWR will manage and protect sufficient acres of cultivated lands such as pasture, grain and hay crops, or alfalfa to provide California horned lark and grasshopper sparrow habitat such that the total acres of habitat impacted in the near-term timeframe are mitigated at a ratio of 2:1 protection. Additional grassland protection, enhancement, and management may be substituted for the protection of cultivated lands.

Impact BIO-131: Effects on California Horned Lark and Grasshopper Sparrow and Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of grasshopper sparrow and California horned lark. AMM20 Greater Sandhill Crane would minimize the risk of bird strikes by installing flight-diverters on new and selected existing powerlines.

NEPA Effects: New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of grasshopper sparrow and California horned lark. With the implementation of AMM20 Greater Sandhill Crane the effect of new transmission lines on California horned lark and grasshopper sparrow would not be adverse.

CEQA Conclusion: New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of grasshopper sparrow and California horned lark. With the incorporation of AMM20 Greater Sandhill Crane, new transmission lines would have a less-than-significant impact on grasshopper sparrow and California horned lark.

Impact BIO-132: Indirect Effects of Plan Implementation on California Horned Lark and Grasshopper Sparrow

Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect California horned lark and grasshopper sparrow use of modeled habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane, Table 4), although there are no available data to determine the extent to which these noise levels could affect California horned lark or grasshopper sparrow. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7, including AMM2 Construction Best Management Practices and Monitoring,
Alternative 1B would minimize the likelihood of such spills. The inadvertent discharge of sediment or excessive dust adjacent to California horned lark and grasshopper sparrow nesting habitat could also have a negative effect on these species. AMM1-AMM7 would ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

**NEPA Effects:** Indirect effects on California horned lark and grasshopper sparrow as a result of Alternative 1B implementation could have adverse effects on these species through the modification of habitat and potential for direct mortality. California horned lark and grasshopper sparrow are not covered species under the BDCP, and the potential for mortality would be adverse without preconstruction surveys to ensure that nests are detected and avoided. In conjunction with AMM1–AMM7, Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

**CEQA Conclusion:** Indirect effects on California horned lark and grasshopper sparrow as a result of Alternative 1B implementation could have a significant impact on these species. The incorporation of AMM1–AMM7 into the BDCP and the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact to a less-than-significant level.

**Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds**

See Mitigation Measure BIO-75 under Impact BIO-75.

**Impact BIO-133: Periodic Effects of Inundation on California Horned Lark and Grasshopper Sparrow as a Result of Implementation of Conservation Components**

Flooding of the Yolo Bypass from Fremont Weir operations (*CM2 Yolo Bypass Fisheries Enhancement*) would increase the frequency and duration of inundation on approximately 1,158-3,650 acres of modeled California horned lark and grasshopper sparrow habitat (Table 12-1B-49). Based on hypothetical footprints, implementation of *CM5 Seasonally Inundated Floodplain Restoration* could result in the periodic inundation of up to approximately 3,823 acres of modeled habitat (Table 12-1B-49).

Reduced foraging habitat availability may be expected during the fledgling period of the nesting season due to periodic inundation. However, inundation would occur during the nonbreeding season and would not be expected to have an adverse effect on either species.

**NEPA Effects:** Periodic inundation of floodplains would not have adverse effects on grasshopper sparrow or California horned lark because inundation is expected to occur prior to the breeding season.

**CEQA Conclusion:** Periodic inundation of floodplains would not have a significant impact on grasshopper sparrow or California horned lark because inundation is expected to occur prior to the breeding season.

**Least Bittern and White-Faced Ibis**

This section describes the effects of Alternative 1B, including water conveyance facilities construction and implementation of other conservation components, on least bittern and white-faced ibis. Modeled breeding habitat for least bittern and white-faced ibis includes tidal freshwater
emergent wetlands, nontidal freshwater emergent wetlands, managed wetlands, and other natural seasonal wetlands in CZs 2, 4, and 11.

Construction and restoration associated with Alternative 1B conservation measures would result in both temporary and permanent losses of modeled habitat for mountain plover as indicated in Table 12-1B-50. Full implementation of Alternative 1B would include the following biological objectives over the term of the BDCP which would also benefit least bittern and white-faced ibis (BDCP Chapter 3, Conservation Strategy).

- Restore or create at least 24,000 acres of tidal freshwater emergent wetland in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1, associated with CM4).
- Create at least 1,200 acres of nontidal marsh consisting of a mosaic of nontidal perennial aquatic and nontidal freshwater emergent wetland natural communities (Objective NFEW/NPANC1.1, associated with CM10).
- Protect and enhance at least 8,100 acres of managed wetland, at least 1,500 acres of which are in the Grizzly Island Marsh Complex (Objective MWNC1.1, associated with CM3).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance habitat for these species and implementation of AMM1–AMM7, AMM27 Selenium Management, and Mitigation Measure BIO-75, impacts on least bittern and white-faced ibis would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

\(^a\) See Appendix 12E for detailed breakdown of conservation measure effects over the BDCP’s near-term and late long-term timeframes.

\(^b\) See discussion below for a description of applicable CMs.

\(^c\) LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

\(^d\) Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

LLT = late long-term
NA = not applicable
Impact BIO-134: Loss or Conversion of Habitat for and Direct Mortality of Least Bittern and White-Faced Ibis

Alternative 1B conservation measures would result in the combined permanent and temporary loss and conversion of up to 13,119 acres of modeled habitat for least bittern and white-faced ibis (13,069 acres of permanent loss and conversion and 50 of temporary loss, Table 12-1B-50). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass enhancements (CM2), and tidal habitat restoration (CM4). Habitat enhancement and management activities (CM11), which would include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate least bittern and white-faced ibis habitat. Each of these individual activities is described below. A summary statement of the combined impacts, NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.

- **CM1 Water Facilities and Operation:** Construction of Alternative 1B conveyance facilities would result in the combined permanent and temporary loss of up to 11 acres of modeled least bittern and white-faced ibis habitat (6 acre of permanent loss, 5 acres of temporary loss) from CZ 4. Permanent losses would occur as a result of constructing the east canal. Small areas of emergent wetland and managed wetland would be removed where the canal would cross manmade channels. The temporary losses would also occur where small patches or stringers of wetlands would be removed for siphon construction. The construction footprint for CM1 does not overlap with any occurrences of least bittern or white-faced ibis. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would be available to address potential effects on least bittern or white-faced ibis if they were to nest in or adjacent to construction areas. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 1B construction locations.

- **CM2 Yolo Bypass Fisheries Enhancement:** Construction of the Yolo bypass fisheries enhancement would permanently remove 55 acres of modeled least bittern and white-faced ibis habitat in the Yolo Bypass in CZ 2. In addition, 45 acres of habitat would be temporarily removed. The loss is expected to occur during the first 10 years of Alternative 1B implementation.

- **CM4 Tidal Natural Communities Restoration:** Tidal habitat restoration site preparation and inundation would permanently remove an estimated 13,008 acres of modeled least bittern and white-faced ibis habitat in CZ 2, 4, and 11 by the late long-term time period.

- **CM11 Natural Communities Enhancement and Management:** A variety of habitat management actions included in CM11 Natural Communities Enhancement and Management that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of least bittern and white-faced ibis habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available least bittern and white-faced ibis habitat.

- **Operations and Maintenance:** Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect least bittern and white-faced ibis use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by
AMM1–AMM7 described below and Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to further reduce potential effects.

- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of least bittern and white-faced ibis because adults and fledged young would be expected to avoid contact with construction and other equipment. However, if either species were to nest in the construction area, equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to address these adverse effects.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

**Near-Term Timeframe**

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. The Plan would remove 5,190 acres of modeled habitat for least bittern and white-faced ibis in the study area in the near-term (5,140 acres of permanent loss, and 50 acres of temporary loss). These effects would result from the construction of the water conveyance facilities (CM1, 11 acres), and the implementation of other conservation measures (Yolo Bypass fisheries enhancement [CM2], and tidal restoration [CM4] 5,179 acres). Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected would be 1:1 for restoration/creation and 1:1 protection of least bittern and white-faced ibis habitat. Using these ratios would indicate that 11 acres of habitat should be restored and 11 acres of habitat should be protected to compensate for the CM1 losses of 11 acres of least bittern and white-faced ibis habitat. The near-term effects of other conservation actions would remove 5,179 acres of modeled habitat, and therefore require 5,179 acres of restoration and 5,179 acres of protection of least bittern and white-faced ibis habitat using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection).

The BDCP has committed to near-term goals of restoring 8,850 acres of tidal freshwater emergent wetland and protecting and enhancing 4,800 acres of managed wetland in the Plan Area (Table 3-4 in Chapter 3). These conservation actions are associated with CM4 and CM3 and would occur in the same timeframe as the construction and early restoration losses, thereby avoiding adverse effects of habitat loss on least bittern and white-faced ibis. The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1 in BDCP Chapter 3, Conservation Strategy) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The 4,800 acres of managed wetland would be protected and enhanced in CZ 11 and would benefit these species through the enhancement of degraded areas (such as areas of bare ground or marsh where the predominant vegetation consists of invasive species such as perennial pepperweed) to vegetation such as pickleweed-alkali heath-American bulrush plant associations (Objective MWNC1.1). In addition, at least 400 acres of nontidal marsh would be created, some of which would provide nesting habitat for least bittern and white-faced ibis. These Plan objectives represent performance standards for considering the effectiveness of restoration and protection actions. The acres of restoration and
protection contained in the near-term Plan goals satisfy the typical mitigation that would be applied to the project-level effects of CM1, as well as mitigate the near-term effects of the other conservation measures.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures. Least bittern and white-faced ibis are not covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided.

**Late Long-Term Timeframe**

Alternative 1B as a whole would result in the permanent loss of and temporary effects on 13,119 acres (13,069 acres of permanent loss, 50 acres of temporary loss) of least bittern and white-faced ibis habitat during the term of the Plan. The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through CM4 Tidal Natural Communities Restoration to restore or create at least 24,000 acres of tidal freshwater emergent wetland in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1). In addition, 1,200 acres of nontidal marsh would be created through CM10 Nontidal Marsh Restoration and 8,100 acres of managed wetland would be protected and enhanced in CZ 11.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures. Least bittern and white-faced ibis are not covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would be available to address this potential effect.

**NEPA Effects:** The loss of least bittern and white-faced ibis habitat and potential mortality of these special status species under Alternative 1B would represent an adverse effect in the absence of other conservation actions. However, with the habitat protection and restoration associated with CM3, CM4, CM6, CM7, and CM11, guided by biological goals and objectives and by AMM1–AMM7, which would be in place throughout the construction period, the effects of habitat loss under on least bittern and white-faced ibis would not be adverse under Alternative 1B. Least bittern and white-faced ibis are not covered species under the BDCP, and the potential for mortality would be adverse without preconstruction surveys to ensure that nests are detected and avoided. Mitigation Measure BIO-75 would be available to address this adverse effect.
**CEQA Conclusion:**

**Near-Term Timeframe**

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the impacts of construction would be less than significant under CEQA. The Plan would remove 5,190 acres of modeled habitat for least bittern and white-faced ibis in the study area in the near-term (5,140 acres of permanent loss, and 50 acres of temporary loss). These effects would result from the construction of the water conveyance facilities (CM1, 11 acres), and the implementation of other conservation measures (Yolo Bypass fisheries enhancement [CM2], and tidal restoration [CM4] 5,179 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected would be 1:1 for restoration/creation and 1:1 protection of least bittern and white-faced ibis habitat. Using these ratios would indicate that 11 acres of habitat should be restored and 11 acres of habitat should be protected to compensate for the CM1 losses of 11 acres of least bittern and white-faced ibis habitat. The near-term effects of other conservation actions would remove 5,179 acres of modeled habitat, and therefore require 5,179 acres of restoration and 5,179 acres of protection of least bittern and white-faced ibis habitat using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection).

The BDCP has committed to near-term goals of restoring 2,000 acres of tidal freshwater emergent wetland and 4,800 acres of managed wetland in the Plan Area (Table 3-4 in Chapter 3). These conservation actions are associated with CM4 and CM3 and would occur in the same timeframe as the construction and early restoration losses, thereby avoiding adverse effects of habitat loss on least bittern and white-faced ibis. The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1 in BDCP Chapter 3, Conservation Strategy) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The 4,800 acres of managed wetland would be protected and enhanced in CZ 11 and would benefit these species through the enhancement of degraded areas (such as areas of bare ground or marsh where the predominant vegetation consists of invasive species such as perennial pepperweed) to vegetation such as pickleweed-alkali heath-American bulrush plant associations (Objective MWNC1.1). In addition, at least 400 acres of nontidal marsh would be created, some of which would provide nesting habitat for least bittern and white-faced ibis. These Plan objectives represent performance standards for considering the effectiveness of restoration and protection actions. The acres of restoration and protection contained in the near-term Plan goals satisfy the typical mitigation that would be applied to the project-level effects of CM1, as well as mitigate the near-term effects of the other conservation measures.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas and storage sites. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures. Least bittern and white-faced ibis are not covered species under the BDCP. For the BDCP
to have a less-than-significant impact on individuals, preconstruction surveys would be required to
ensure that nests were detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction
Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce the potential impact on
nesting least bittern and white-faced ibis to a less-than-significant impact.

**Late Long-Term Timeframe**

Alternative 1B as a whole would result in the permanent loss of and temporary effects on 13,119
acres (13,069 acres of permanent loss, 50 acres of temporary loss) of least bittern and white-faced
ibis habitat during the term of the Plan. The locations of these losses are described above in the
analyses of individual conservation measures. The Plan includes conservation commitments
through *CM4 Tidal Natural Communities Restoration* to restore or create at least 24,000 acres of tidal
freshwater emergent wetland in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1). In addition, 1,200
acres of nontidal marsh would be created through *CM10 Nontidal Marsh Restoration* and 8,100 acres
of managed wetland would be protected and enhanced in CZ 11.

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2
Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention
Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and
Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged
Material*, and *AMM7 Barge Operations Plan*. All of these AMMs include elements that avoid or
minimize the risk of affecting individuals and species habitats adjacent to work areas and storage
sites. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization
Measures*. Least bittern and white-faced ibis are not covered species under the BDCP. For the BDCP
to avoid having a significant impact on individuals, preconstruction surveys for noncovered avian
species would be required to ensure that nests were detected and avoided. Mitigation Measure BIO-75
would reduce the potential impact on nesting least bittern and white-faced ibis and to a less-
than-significant level.

Considering these protection and restoration provisions, which would provide acreages of new
high-value or enhanced habitat in amounts suitable to compensate for habitats lost to construction
and restoration activities, and with the implementation of AMM1–AMM7 and Mitigation Measure
BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, the loss
of habitat or direct mortality through implementation of Alternative 1B would not result in a
substantial adverse effect through habitat modifications and would not substantially reduce the
number or restrict the range of the species. Therefore, the loss of habitat or potential mortality
under this alternative would have a less-than-significant impact on least bittern and white-faced
ibis.

**Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid
Disturbance of Nesting Birds**

See Mitigation Measure BIO-75 under Impact BIO-75.

**Impact BIO-135: Effects on Least Bittern and White-Faced Ibis Associated with Electrical
Transmission Facilities**

New transmission lines would increase the risk for bird-power line strikes, which could result in
injury or mortality of least bittern and white-faced ibis. The risk for bird-power line strikes would be
minimized with the incorporation of *AMM20 Greater Sandhill Crane* into the BDCP. This measure
would ensure that conductor and ground lines are fitted with flight diverters in compliance with the best available practices, such as those specified in the USFWS Avian Protection Guidelines.

**NEPA Effects:** New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of least bittern and white-faced ibis. With the incorporation of AMM20 Greater Sandhill Crane into the BDCP, new transmission lines would not have an adverse effect on least bittern and white-faced ibis.

**CEQA Conclusion:** New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of least bittern and white-faced ibis. With the incorporation of AMM20 Greater Sandhill Crane into the BDCP, new transmission lines would have a less-than-significant impact on least bittern and white-faced ibis.

**Impact BIO-136: Indirect Effects of Plan Implementation on Least Bittern and White-Faced Ibis**

**Indirect construction- and operation-related effects:** Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect least bittern and white-faced ibis use of modeled habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect least bittern or white-faced ibis. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7, including AMM2 Construction Best Management Practices and Monitoring, would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to least bittern and white-faced ibis could also have a negative effect on these species. AMM1–AMM7 would ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

**Methylmercury Exposure:** Marsh (tidal and nontidal) and floodplain restoration have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury (see BDCP Chapter 3, Conservation Strategy, for details of restoration). Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community and floodplain restoration could indirectly affect least bittern and white-faced ibis, via uptake in lower tropic levels (as described in the BDCP, Appendix 5.D, *Contaminants*).

In addition, the potential mobilization or creation of methylmercury within the Plan Area varies with site-specific conditions and would need to be assessed at the project level. **CM12 Methylmercury**
Terrestrial Biological Resources

Alternative 1B

Management contains provisions for project-specific Mercury Management Plans. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would be available to address the uncertainty of methylmercury levels in restored tidal marsh and potential impacts on least bittern and white-faced ibis.

**Selenium Exposure:** Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher levels of selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including least bittern and white-faced ibis. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Changes in selenium concentrations were analyzed in Chapter 8, *Water Quality*, and it was determined that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4 and CM5) would lead to adverse effects on least bittern and white-faced ibis.

Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on least bittern and white-faced ibis from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of AMM27 Selenium Management (BDCP Appendix 3.C, *Avoidance and Minimization Measures*) which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be
evaluated separately for each restoration effort as part of design and implementation. This
avoidance and minimization measure would be implemented as part of the tidal habitat restoration
design schedule.

**NEPA Effects:** Indirect effects on least bittern and white-faced ibis as a result of constructing the
water conveyance facilities could have adverse effects on these species in the absence of other
conservation actions. However, the implementation of AMM1–AMM7 would help to reduce this
effect. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would also be available to address the adverse indirect effects of
construction on active nests. Tidal habitat restoration could result in increased exposure of least
bittern and white-faced ibis to selenium. This effect would be addressed through the
implementation of *AMM27 Selenium Management*, which would provide specific tidal habitat
restoration design elements to reduce the potential for bioaccumulation of selenium and its
bioavailability in tidal habitats.

Increased methylmercury associated with natural community and floodplain restoration could
indirectly affect least bittern and white-faced ibis, via uptake in lower tropic levels (as described in
the BDCP, Appendix 5.D, *Contaminants*). However, it is unknown what concentrations of
methylmercury are harmful to the species, and the potential for increased exposure varies
substantially within the study area. *CM12 Methylmercury Management* contains provisions for
project-specific Mercury Management Plans. Site-specific restoration plans that address the creation
and mobilization of mercury, as well as monitoring and adaptive management as described in CM12
would better inform potential adverse effects and address the uncertainty of methylmercury levels
in restored tidal marsh in the study area. The site-specific planning phase of marsh restoration
would be the appropriate place to assess the potential for risk of methylmercury exposure for least
bittern and white-faced ibis, once site specific sampling and other information could be developed.

**CEQA Conclusion:** Indirect effects on least bittern and white-faced ibis as a result of constructing the
water conveyance facilities could have a significant impact on these species. The incorporation of
AMM1–AMM7 into the BDCP and the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this
impact to a less-than-significant level. Increased methylmercury associated with natural community
and floodplain restoration could indirectly affect least bittern and white-faced ibis, via uptake in
lower tropic levels (as described in the BDCP, Appendix 5.D, *Contaminants*). In addition, the
potential mobilization or creation of methylmercury within the Plan Area varies with site-specific
conditions and would need to be assessed at the project level. *CM12 Methylmercury Management*
contains provisions for project-specific Mercury Management Plans. Tidal habitat restoration could
result in increased exposure of least bittern and white-faced ibis to selenium. This effect would be
addressed through the implementation of *AMM27 Selenium Management*, which would provide
specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of
selenium and its bioavailability in tidal habitats. Therefore, the indirect effects of Alternative 1B
implementation would not have an significant impact on least bittern and white-faced ibis.

**Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds**

See Mitigation Measure BIO-75 under Impact BIO-75.
Impact BIO-137: Periodic Effects of Inundation on Least Bittern and White-Faced Ibis as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from Fremont Weir operations (CM2 Yolo Bypass Fisheries Enhancement) would increase the frequency and duration of inundation on approximately 961-2,672 acres of modeled least bittern and white-faced ibis habitat (Table 12-1B-50). However, no adverse effects of increased inundation frequency on nesting habitat are expected because wetland vegetation has persisted under the existing Yolo Bypass flooding regime, and changes to frequency and inundation are within the tolerance of these vegetation types. Inundation would occur in the nonbreeding season and wetlands supporting habitat would not be expected to be affected by flood flows.

NEPA Effects: Periodic inundation of Yolo Bypass would not be expected to have adverse effects on least bittern or white-faced ibis because wetland vegetation has persisted under the existing Yolo Bypass flooding regime, and changes to frequency and inundation are within the tolerance of these vegetation types.

CEQA Conclusion: Periodic inundation of Yolo Bypass would not be expected to have a significant impact on least bittern or white-faced ibis because wetland vegetation has persisted under the existing Yolo Bypass flooding regime, and changes to frequency and inundation are within the tolerance of these vegetation types.

Loggerhead Shrike

This section describes the effects of Alternative 1B, including water conveyance facilities construction and implementation of other conservation components, on loggerhead shrike. Modeled habitat for loggerhead shrike includes both high-value and low-value modeled habitat. High-value habitat includes grassland, vernal pool complex and alkali seasonal wetland natural communities in addition to cultivated lands, including pasture and grain and hay crops. Low-value habitat includes row crops such as truck and berry crops and field crops which are not considered to be valuable habitat for the species but were included in the model as they may provide foraging opportunities.

Construction and restoration associated with Alternative 1B would result in both temporary and permanent losses of modeled habitat for loggerhead shrike as indicated in Table 12-1B-51. Construction and restoration associated with Alternative 1B conservation measures would include the following biological objectives over the term of the BDCP which would also benefit loggerhead shrike (BDCP Chapter 3, Conservation Strategy).

- Protect at least 8,000 acres of grassland with at least 2,000 acres protected in CZ 1, at least 1,000 acres protected in CZ 8, at least 2,000 acres protected in CZ 11, and the remainder distributed among CZs 1, 2, 4, 5, 7, 8, and 11 (Objective GNC1.1, associated with CM3).
- Restore at least 2,000 acres of grasslands (Objective GNC1.2, associated with CM8).
- Protect at least 150 acres of alkali seasonal wetland and at least 600 acres of existing vernal pool complex in CZs 1, 8, and/or 11 (Objectives ASWNC1.1 and VPNC1.1, associated with CM3).
- Increase prey availability and accessibility for grassland-foraging species (Objectives ASWNC2.4, VPNC2.5, and GNC2.4, associated with CM11).
- Protect at least 48,625 acres of cultivated lands that provide suitable habitat for covered and other native wildlife species (Objective CLNC1.1, associated with CM3).
Maintain and protect the small patches of important wildlife habitats associated with cultivated lands that occur in cultivated lands within the reserve system, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Objective CLNC1.3, associated with CM3).

Establish 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands at a minimum rate of 400 linear feet per 100 acres (Objective SH2.2, associated with CM11).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities that would enhance habitat for the species and implementation of AMM1–AMM7 and Mitigation Measure BIO-75, impacts on loggerhead shrike would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

\(^a\) See Appendix 12E for detailed breakdown of conservation measure effects over the BDCP’s near-term and late long-term timeframes.

\(^b\) See discussion below for a description of applicable CMs.

\(^c\) LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

\(^d\) Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

Impact BIO-138: Loss or Conversion of Modeled Habitat for and Direct Mortality of Loggerhead Shrike

Alternative 1B conservation measures would result in the combined permanent loss or conversion and temporary loss of up to 59,116 acres of modeled habitat for loggerhead shrike (33,375 acres of which would be high-value habitat and 25,741 acres of which would be low-value habitat, Table 12-
Alternative 1B-51). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass fisheries improvements (CM2), tidal habitat restoration (CM4), floodplain restoration (CM5), channel margin enhancement (CM6), riparian restoration, (CM7), grassland restoration (CM8), vernal pool and wetland restoration (CM9), nontidal marsh restoration (CM10), natural communities enhancement and management (CM11) and construction of conservation hatcheries (CM18). The majority of habitat loss (33,244 acres) would result from CM4. Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, and the construction of recreational trails, signs, and facilities, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate loggerhead shrike modeled habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.

- **CM1 Water Facilities and Operation:** Construction of Alternative 1B conveyance facilities would result in the combined permanent and temporary loss of up to 15,172 acres of modeled loggerhead shrike habitat. This would be comprised of 7,490 acres of high-value habitat (2,962 permanent loss or conversion, 4,528 temporary loss or conversion) and 7,862 acres of low-value cultivated lands (2,626 permanent loss, 5,236 temporary loss) from CZ 4, CZ 5, CZ 6, CZ 7, and CZ 8. Impacts would primarily occur from the construction of the new forebay and associated borrow and spoil area in CZ 8. Other habitat losses would occur as a result of construction of the canal and associated borrow and spoil areas, and from the construction of the intakes in the north Delta. The largest impact from CM1 on loggerhead shrike would occur in CZ 8, where there are larger stands of ruderal and herbaceous vegetation and California annual grassland, which provides high-value habitat for the species. Approximately 685 acres of impact would be from the new forebay constructed south of the Clifton Court Forebay in CZ 8. Loggerhead shrikes nest in high abundance in these grasslands to the south and to the west of Clifton Court Forebay. Shrikes were detected using this area at a much higher rate than other grasslands and areas in the Delta during DHCCP surveys (Appendix 12C, 2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report). The CM1 footprint overlaps with six loggerhead shrike occurrences, all in CZ 8. The construction of the new forebay overlaps with five occurrences and there is one occurrence that overlaps with the footprint of a temporary transmission line. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would require preconstruction surveys and the establishment of no-disturbance buffers and would be available to address potential effects on loggerhead shrikes if they were to nest in or adjacent to construction areas. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 1B construction locations. Construction of the water conveyance facilities would occur in the near-term timeframe.

- **CM2 Yolo Bypass Fisheries Enhancement:** Construction of the Yolo bypass fisheries enhancement would result in the combined permanent and temporary loss of up to 1,274 acres of high-value loggerhead shrike habitat (898 acres of permanent loss, 376 acres of temporary loss) in the Yolo Bypass in CZ 2. In addition, 182 acres of low-value habitat would be removed (85 acres of permanent loss, 97 acres of temporary loss). The loss is expected to occur during the first 10 years of Alternative 1B implementation.

- **CM4 Tidal Natural Communities Restoration:** Tidal habitat restoration (CM4) site preparation and inundation would permanently remove an estimated 20,880 acres of high-value loggerhead
Alternative 1B
Terrestrial Biological Resources

shrike habitat and 12,364 acres of low-value habitat. The majority of the acres lost would
consist of cultivated lands in CZs 1, 2, 4, 5, 6, and/or 7. Grassland losses would likely occur in the
vicinity of Cache Slough, on Decker Island in the West Delta ROA, on the upslope fringes of
Suisun Marsh, and along narrow bands adjacent to waterways in the South Delta ROA. Tidal
restoration would directly impact and fragment grassland just north of Rio Vista in and around
French and Prospect Islands, and in an area south of Rio Vista around Threemile Slough. Losses
of alkali seasonal wetland complex habitat would likely occur in the south end of the Yolo
Bypass and on the northern fringes of Suisun Marsh.

• **CM5 Seasonally Inundated Floodplain Restoration: Construction of setback levees to restore**
seasonally inundated floodplain would permanently and temporarily remove approximately
1,450 acres of high-value loggerhead shrike habitat (933 permanent, 517 temporary). These
losses would be expected after the first 10 years of Alternative 1B implementation along the San
Joaquin River and other major waterways in CZ 7.

• **CM7 Riparian Natural Community Restoration:** Riparian restoration would permanently remove
approximately 370 acres of high-value loggerhead shrike habitat as part of tidal restoration and
1,489 acres as part of seasonal floodplain restoration. In addition, 503 acres of low-value habitat
would be removed as a part of tidal restoration and 1,971 acres would be removed as part of
seasonal floodplain restoration through CM7.

• **CM8 Grassland Natural Community Restoration and CM9 Vernal Pool and Alkali Seasonal Wetland
Complex Restoration:** Temporary construction-related disturbance of grassland habitat would
result from implementation of CM8 and CM9 in in CZs 1, 2, 4, 5, 7, 8, and 11. However, all areas
would be restored after the construction periods. Grassland restoration would be implemented
on agricultural lands that also provide habitat for loggerhead shrike and would result in the
conversion of 1,849 acres of cultivated lands to high-value grassland.

• **CM10 Nontidal Marsh Restoration:** Implementation of CM10 would result in the permanent
removal of 705 acres of high-value loggerhead shrike habitat and 735 acres of low-value
loggerhead shrike habitat.

• **CM11 Natural Communities Enhancement and Management:** A variety of habitat management
actions included in CM11 that are designed to enhance wildlife values in restored or protected
habitats could result in localized ground disturbances that could temporarily remove small
amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative
vegetation and road and other infrastructure maintenance activities, would be expected to have
minor adverse effects on available habitat and would be expected to result in overall
improvements to and maintenance of habitat values over the term of the BDCP. CM11 would
also include the construction of recreational-related facilities including trails, interpretive signs,
and picnic tables (BDCP Chapter 4, *Covered Activities and Associated Federal Actions*). The
construction of trailhead facilities, signs, staging areas, picnic areas, bathrooms, etc. would be
placed on existing, disturbed areas when and where possible. However, approximately 50 acres
of grassland habitat would be lost from the construction of trails and facilities.

Habitat management- and enhancement-related activities could disturb loggerhead shrike nests.
If either species were to nest in the vicinity of a worksite, equipment operation could destroy
nests, and noise and visual disturbances could lead to their abandonment, resulting in mortality
of eggs and nestlings. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys
and Avoid Disturbance of Nesting Birds*, would be available to address these adverse effects.
- **CM18 Conservation Hatcheries**: Implementation of CM18 would remove up to 35 acres of high-value loggerhead shrike habitat for the development of a delta and longfin smelt conservation hatchery in CZ 1. Hatchery construction is expected to occur within the first 10 years of Plan implementation.

- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect loggerhead shrike use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7, Mitigation Measure BIO-75, and conservation actions as described below.

- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged loggerhead shrike if they were present in the Plan Area, because they would be expected to avoid contact with construction and other equipment. If either species were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to address these adverse effects.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also included.

**Near-Term Timeframe**

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. The Plan would remove 13,316 acres (8,412 permanent, 4,904 temporary) of high-value habitat for loggerhead shrike in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 7,490 acres), and implementing other conservation measures (CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, CM5 Seasonally Inundated Floodplain Restoration, CM7 Riparian Natural Community Restoration, CM8 Grassland Natural Community Restoration, CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration, CM11 Natural Communities Enhancement and Management and CM18 Conservation Hatcheries—5,826 acres). In addition, 9,761 acres (4,427 permanent, 5,333 temporary) of low-value habitat would be removed or converted in the near-term (CM1, 5,045 acres; CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, CM7 Riparian Natural Community Restoration, CM8 Grassland Natural Community Restoration, CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration, CM11 Natural Communities Enhancement and Management and CM18 Conservation Hatcheries—1,898 acres).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 protection of high-value habitat. Using this ratio would indicate that 14,980 acres should be protected to compensate for the loss of high-value habitat from CM1. The near-term effects of other conservation actions would require 11,652 acres of protection to compensate for the loss of high-value shrike habitat using the same typical NEPA and CEQA ratio (2:1 protection for the loss of high-value habitat). The loss of low-value habitat would not require mitigation because a
large proportion of the low-value habitat would result from the conversion and enhancement to
high-value habitats. In addition, temporary impacts on cultivated lands would be restored relatively
quickly after completion of construction.

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of
grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of
alkali seasonal wetland complex, and protecting 15,400 acres of non-rice cultivated lands (Table 3-4
in Chapter 3). These conservation actions are associated with CM3, CM8, and CM9 and would occur
in the same timeframe as the construction and early restoration losses.

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1
and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali
seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous
matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would
create larger, more expansive patches of high-value habitat for loggerhead shrike and reduce the
effects of current levels of habitat fragmentation. Under CM11 Natural Communities Enhancement
and Management, insect prey populations would be increased on protected lands, enhancing the
foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4).

Cultivated lands that provide habitat for covered and other native wildlife species would provide
approximately 15,400 acres of potential high-value habitat for loggerhead shrike (Objective
CLNC1.1). In addition, there is a commitment in the plan (Objective CLNC1.3) to maintain and
protect small patches of trees and shrubs within cultivated lands that would maintain foraging
perches and nesting habitat for the species. The establishment of 20- to 30-foot-wide hedgerows
along field borders and roadsides within protected cultivated lands would also provide high-value
nesting habitat for loggerhead shrike (Objective SH2.2). These Plan objectives represent
performance standards for considering the effectiveness of conservation actions.

The combined acres of restoration and protection of 3,660 acres of grassland, vernal pool complex,
and alkali seasonal wetland contained in the near-term Plan goals and the additional detail in the
biological objectives satisfy the typical mitigation that would be applied to the project-level effects of
CM1. However, some portion of the 15,400 acres of cultivated lands protected in the near-term
timeframe would need to include suitable high-value crop types for loggerhead shrike to avoid an
adverse effect of habitat loss from CM1. The conservation commitment is 7,572 acres short of
meeting the compensation for other near-term effects on loggerhead shrike high-value habitat.

Mitigation Measure BIO-138, Compensate for the Near-Term Loss of High-Value Loggerhead Shrike
Habitat, would be available to address the adverse effect of near-term high-value habitat loss by
providing crop management requirements for CM1 compensation and requiring additional acreage
compensation for the other near-term effects. The management and enhancement of cultivated
lands including insect prey enhancement through CM3 and CM11, the protection of shrubs and
establishment of hedgerows within protected cultivated lands would compensate for any potential
effect from the loss of low-value loggerhead shrike foraging habitat.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2
Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention
Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and
Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged
Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or
minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are
described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.
The loggerhead shrike is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

**Late Long-Term Timeframe**

Alternative 1B as a whole would result in the combined permanent and temporary effects on 34,631 acres of high-value habitat and 25,741 acres of low-value loggerhead shrike habitat over the term of the Plan. The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through *CM3 Natural Communities Protection and Restoration, CM8 Grassland Natural Community Restoration*, and *CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration* to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3). Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would create larger, more expansive patches of high-value habitat for loggerhead shrike and reduce the effects of current levels of habitat fragmentation. Under *CM11 Natural Communities Enhancement and Management*, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 48,625 acres of potential high-value habitat for loggerhead shrike (Objective CLNC1.1). In addition, there is a commitment in the plan (Objective CLNC1.3) to maintain and protect small patches of trees and shrubs within cultivated lands that would maintain foraging perches and nesting habitat for the species. The establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands would also provide high-value nesting habitat for loggerhead shrike (Objective SH2.2).

The Plan also includes commitments to implement *AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material*, and *AMM7 Barge Operations Plan*. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*. The loggerhead shrike is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

**NEPA Effects**: The loss of loggerhead shrike habitat and potential for mortality of this special-status species under Alternative 1B would represent an adverse effect in the absence of other conservation actions. However, with habitat protection and restoration associated with CM3, CM8, CM9, and CM11, guided by biological goals and objectives and AMM1–AMM7, and with implementation of...
Mitigation Measure BIO-138, *Compensate for the Near-Term Loss of High-Value Loggerhead Shrike Habitat*, which would be available to guide the near-term protection and management of cultivated lands, the effects of habitat loss on loggerhead shrike under Alternative 1B would not be adverse. Loggerhead shrike is not a covered species under the BDCP, and the potential for mortality would be an adverse effect without preconstruction surveys to ensure that nests are detected and avoided. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address this adverse effect.

**CEQA Conclusion:**

**Near-Term Timeframe**

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. The Plan would remove 13,316 acres (8,412 permanent, 4,904 temporary) of high-value habitat for loggerhead shrike in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 7,490 acres), and implementing other conservation measures (*CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, CM5 Seasonally Inundated Floodplain Restoration, CM7 Riparian Natural Community Restoration, CM8 Grassland Natural Community Restoration, CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration, CM11 Natural Communities Enhancement and Management and CM18 Conservation Hatcheries*—5,826 acres). In addition, 9,761 acres (4,427 permanent, 5,333 temporary) of low-value habitat would be removed or converted in the near-term (CM1, 5,045 acres; *CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, CM7 Riparian Natural Community Restoration, CM8 Grassland Natural Community Restoration, CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration, CM11 Natural Communities Enhancement and Management and CM18 Conservation Hatcheries*—1,898 acres).

The typical NEPA and CEQA project-level mitigation ratio for those natural communities affected would be 2:1 protection of high-value habitat. Using this ratio would indicate that 14,980 acres should be protected to compensate for the loss of high-value habitat from CM1. The near-term effects of other conservation actions would require 11,652 acres of protection to compensate for the loss of high-value shrike habitat using the same typical NEPA and CEQA ratio (2:1 protection for the loss of high-value habitat). The loss of low-value habitat would not require mitigation because a large proportion of the low-value habitat would result from the conversion and enhancement to high-value habitats. In addition, temporary impacts on cultivated lands would be restored relatively quickly after completion of construction.

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,400 acres of non-rice cultivated lands (Table 3-4 in Chapter 3). These conservation actions are associated with CM3, CM8, and CM9 and would occur in the same timeframe as the construction and early restoration losses.

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZs 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which...
would create larger, more expansive patches of high-value habitat for loggerhead shrike and reduce the effects of current levels of habitat fragmentation. Under **CM11 Natural Communities Enhancement and Management**, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VNPC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 15,400 acres of potential high-value habitat for loggerhead shrike (Objective CLNC1.1). In addition, there is a commitment in the plan (Objective CLNC1.3) to maintain and protect small patches of trees and shrubs within cultivated lands that would maintain foraging perches and nesting habitat for the species. The establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands would also provide high-value nesting habitat for loggerhead shrike (Objective SH2.2). These Plan objectives represent performance standards for considering the effectiveness of conservation actions.

The combined acres of restoration and protection of 3,660 acres of grassland, vernal pool complex, and alkali seasonal wetland contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1. However, some portion of the 15,400 acres of cultivated lands protected in the near-term timeframe would need to include suitable high-value crop types for loggerhead shrike to avoid the significant impact of habitat loss from CM1. The conservation commitment is 7,572 acres short of meeting the mitigation needed to compensate for other near-term effects on loggerhead shrike high-value habitat. Mitigation Measure BIO-138, **Compensate for the Near-Term Loss of High-Value Loggerhead Shrike Habitat**, would address the significant impact of near-term high-value habitat loss by providing crop management requirements for CM1 compensation and requiring additional acreage compensation for the other near-term effects. With the implementation of Mitigation Measure BIO-138, the loss of high-value habitat would be reduced to a less-than-significant impact. With the management and enhancement of cultivated lands including insect prey enhancement through CM3 and CM11, the protection of shrubs and establishment of hedgerows within protected cultivated lands would compensate for any impact from the loss of low-value loggerhead shrike foraging habitat.

The Plan also includes commitments to implement **AMM1 Worker Awareness Training**, **AMM2 Construction Best Management Practices and Monitoring**, **AMM3 Stormwater Pollution Prevention Plan**, **AMM4 Erosion and Sediment Control Plan**, **AMM5 Spill Prevention, Containment, and Countermeasure Plan**, **AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material**, and **AMM7 Barge Operations Plan**. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, **Avoidance and Minimization Measures**.

The loggerhead shrike is not a covered species under the BDCP and in order to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, **Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds**, would reduce this potential impact to a less-than-significant level.

**Late Long-Term Timeframe**

Alternative 1B as a whole would result in the permanent loss of and temporary effects on 34,631 acres of high-value loggerhead shrike habitat during the term of the Plan. In addition, 21,047 acres of low-value loggerhead shrike habitat would be impacted. The locations of these losses are
described above in the analyses of individual conservation measures. The Plan includes
conservation commitments through **CM3 Natural Communities Protection and Restoration, CM8 Grassland Natural Communities Restoration, and CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration** to protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3). Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2). Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would create larger, more expansive patches of high-value habitat for loggerhead shrike and reduce the effects of current levels of habitat fragmentation. Under **CM11 Natural Communities Enhancement and Management**, insect prey populations would be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Cultivated lands that provide habitat for covered and other native wildlife species would provide approximately 48,625 acres of potential high-value habitat for loggerhead shrike (Objective CLNC1.1). In addition, there is a commitment in the plan (Objective CLNC1.3) to maintain and protect small patches of trees and shrubs within cultivated lands that would maintain foraging perches and nesting habitat for the species. The establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands would also provide high-value nesting habitat for loggerhead shrike (Objective SH2.2).

The Plan also includes commitments to implement **AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan**. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, **Avoidance and Minimization Measures**. The loggerhead shrike is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, **Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds**, would reduce this potential impact to a less-than-significant level.

Considering Alternative 1B’s protection and restoration provisions, which would provide acreages of new high-value or enhanced habitat in amounts suitable to compensate for habitats lost to construction and restoration activities, and with the implementation of AMM1–AMM7, Mitigation Measure BIO-75, **Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds**, and Mitigation Measure BIO-138, **Compensate for the Near-Term Loss of High-Value Loggerhead Shrike Habitat**, the loss of habitat or direct mortality through implementation of Alternative 1B would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on loggerhead shrike.
Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Mitigation Measure BIO-138: Compensate for the Near-term Loss of High-Value Loggerhead Shrike Habitat

Because the BDCP does not include acreage commitments for the protection of crop types in the near-term time period, DWR will manage and protect sufficient acres of cultivated lands such as pasture, grain and hay crops, or alfalfa as high-value loggerhead shrike habitat such that the total acres of high-value habitat impacted in the near-term timeframe are mitigated at a ratio of 2:1. Additional grassland protection, enhancement, and management may be substituted for the protection of high-value cultivated lands.

Impact BIO-139: Effects on Loggerhead Shrike Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of loggerhead shrike. The risk for bird-power line strikes would be minimized with the incorporation of AMM20 Greater Sandhill Crane into the BDCP. This measure would ensure that conductor and ground lines are fitted with flight diverters in compliance with the best available practices, such as those specified in the USFWS Avian Protection Guidelines and would further ensure no adverse effect from electrical transmission facilities.

NEPA Effects: New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of loggerhead shrike. With the implementation of AMM20 Greater Sandhill Crane the effect of new transmission lines on loggerhead shrike would not be adverse.

CEQA Conclusion: New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of loggerhead shrike. With the incorporation of AMM20 Greater Sandhill Crane into the BDCP, new transmission lines would have a less-than-significant impact on loggerhead shrike.

Impact BIO-140: Indirect Effects of Plan Implementation on Loggerhead Shrike

Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect loggerhead shrike use of modeled habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5J.D, Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane, Table 4), although there are no available data to determine the extent to which these noise levels could affect loggerhead shrike. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Indirect effects from construction of the new forebay in CZ 8 could result in substantial effects on active loggerhead shrike nests. DHCCP surveys in 2009 detected 10 nest sites south-west of the Clifton Court Forebay (Appendix 12C, 2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report) and the large expanses of grassland in CZ 8 provide high-value nesting habitat for the species. Mitigation Measure BIO-75,
Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance facilities construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7, including AMM2 Construction Best Management Practices and Monitoring, would minimize the likelihood of such spills. The inadvertent discharge of sediment or excessive dust adjacent to loggerhead shrike nesting habitat could also have a negative effect on these species. AMM1–AMM7 would ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

NEPA Effects: Indirect effects on loggerhead shrike as a result of Plan implementation could have adverse effects on these species through the modification of habitat and potential for direct mortality. The loggerhead shrike is not a covered species under the BDCP and the potential for mortality would be adverse without preconstruction surveys to ensure that nests are detected and avoided. Construction of the new forebay in CZ 8 would have the potential to disrupt nesting loggerhead shrikes in the highly suitable habitat surrounding Clifton Court Forebay and adjacent to work areas. In conjunction with AMM1–AMM7, Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would be available to address this adverse effect.

CEQA Conclusion: Indirect effects on loggerhead shrike as a result of Alternative 1B implementation could have a significant impact on these species. Construction of the new forebay in CZ 8 would have the potential to disrupt nesting loggerhead shrikes in the highly suitable habitat surrounding Clifton Court Forebay and adjacent to work areas. The incorporation of AMM1–AMM7 into the BDCP and the implementation of Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would reduce this impact to a less-than-significant level.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-141: Periodic Effects of Inundation on Loggerhead Shrike as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from Fremont Weir operations (CM2 Yolo Bypass Fisheries Enhancement) would increase the frequency and duration of inundation on 1,830–5,646 acres of modeled loggerhead shrike habitat (consisting of approximately 777–2,423 acres of high-value habitat; Table 12-1B-51).

Based on hypothetical footprints, implementation of CM5 Seasonally Inundated Floodplain Restoration, could result in the periodic inundation of up to approximately 8,138 acres of modeled habitat (Table 12-1B-51), consisting of 3,823 acres of high-value and 4,315 acres of low-value habitat.

Reduced foraging habitat availability may be expected during the fledgling period of the nesting season due to periodic inundation. However, increased frequency and duration of inundation would occur during the nonbreeding season.

NEPA Effects: Periodic inundation of floodplains would not result in an adverse effect on loggerhead shrike from the modification of habitat. Reduced foraging habitat availability may be expected.
during the fledgling period of the nesting season due to periodic inundation. However, increased
frequency and duration of inundation would occur during the nonbreeding season.

**CEQA Conclusion:** Periodic inundation of floodplains would result in a less-than-significant impact
on loggerhead shrike from the modification of habitat. Reduced foraging habitat availability may be
expected during the fledgling period of the nesting season due to periodic inundation. However,
increased frequency and duration of inundation would occur during the nonbreeding season.

**Song Sparrow “Modesto” Population**

This section describes the effects of Alternative 1B, including water conveyance facilities
construction and implementation of other conservation components, on Modesto song sparrow. The
Modesto song sparrow is common and ubiquitous throughout the study area, excluding CZ 11, and
modeled habitat for the species includes managed wetlands, tidal freshwater emergent, nontidal
freshwater emergent, and valley/fothill riparian vegetation communities.

Construction and restoration associated with Alternative 1B conservation measures would result in
both temporary and permanent removal of Modesto song sparrow habitat in the quantities
indicated in Table 12-1B-52. However, Alternative 1B is expected to have little impact on the
population. Full implementation of Alternative 1B would include the following biological objectives
over the term of the BDCP which would benefit Modesto song sparrow (BDCP Chapter 3,
Conservation Strategy).

- Restore or create at least 5,000 acres of valley/fothill riparian natural community, with at least
  3,000 acres occurring on restored seasonally inundated floodplain (Objective VFRNC1.1,
  associated with CM7).
- Protect at least 750 acres of existing valley/fothill riparian natural community in CZ 7 by year
  10 (Objective VFRNC1.2, associated with CM3).
- Restore or create at least 24,000 acres of tidal freshwater emergent wetland in CZ 1, 2, 4, 5, 6,
  and/or 7 (Objective TFEWNC1.1, associated with CM4).
- Create at least 1,200 acres of nontidal marsh consisting of a mosaic of nontidal perennial aquatic
  and nontidal freshwater emergent wetland natural communities (Objective NFEW/NPANC1.1,
  associated with CM10)
- Create 500 acres of managed wetlands in CZ 3, 4, 5, or 6 (Objectives GSHC1.3 and GSHC1.4,
  associated with CM10).
- Increase prey availability and accessibility for grassland-foraging species (Objectives
  ASWNC2.4,VPNC2.5, and GNC2.4, associated with CM11).
- Maintain and protect the small patches of important wildlife habitats associated with cultivated
  lands that occur in cultivated lands within the reserve system, including isolated valley oak
  trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors,
  water conveyance channels, grasslands, ponds, and wetlands (Objective CLNC1.3, associated
  with CM3).
- Establish 20- to 30-foot-wide hedgerows along field borders and roadsides within protected
  cultivated lands at a minimum rate of 400 linear feet per 100 acres (Objective SH2.2, associated
  with CM3).
As explained below, with the restoration or protection of these amounts of habitat, in addition to implementation of AMM1–AMM7 and Mitigation Measure BIO-75, impacts on Modesto song sparrow would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

a See Appendix 12E for detailed breakdown of conservation measure effects over the BDCP’s near-term and late long-term timeframes.

b See discussion below for a description of applicable CMs.

c LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

d Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-142: Loss or Conversion of Habitat for and Direct Mortality of Modesto Song Sparrow

Alternative 1B conservation measures would result in the combined permanent and temporary loss of up to 3,568 acres of modeled habitat for Modesto song sparrow (of which 3,327 acres would be a permanent loss and 241 acres would be a temporary loss of habitat, Table 12-1B-52). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass improvements (CM2), tidal habitat restoration (CM4), and floodplain restoration (CM5). Habitat enhancement and management activities (CM11), which would include ground disturbance and removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate Modesto song sparrow modeled habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follows the individual conservation measure discussions.

- **CM1 Water Facilities and Operation**: Construction of Alternative 1B conveyance facilities would result in the combined permanent and temporary loss of up to 146 acres of modeled Modesto song sparrow habitat (74 acres of permanent loss, 72 acres of temporary loss) from CZ 4, CZ 5,
CZ 6, CZ 7, and CZ 8. The permanent footprint for CM1 overlaps with 19 occurrences of Modesto song sparrow. Fourteen occurrences would be impacted by the construction of the canal, and the other impacts would occur from the forebay, potential borrow or spoil sites, siphon work areas, the permanent transmission line footprint, and a reusable tunnel material storage area. In addition, the temporary footprint overlaps with 42 occurrences of song sparrow. Thirty-six of these occurrences would be impacted by siphon work areas, two would be impacted by intake work areas, and the other 4 occurrences would be impacted by a tunnel work area. Mitigation Measure B10-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would require preconstruction surveys and the establishment of no-disturbance buffers and would be available to address adverse effects on nesting Modesto song sparrows. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 1B construction locations.

Construction of the water conveyance facilities would occur within the first 10 years of Alternative 1B implementation.

- **CM2 Yolo Bypass Fisheries Enhancement:** Construction of the Yolo bypass fisheries enhancement would permanently remove 143 acres of modeled Modesto song sparrow habitat in the Yolo Bypass in CZ 2. In addition, 133 acres of habitat would be temporarily removed. These losses would occur in the near-term timeframe and primarily consist of valley/foothill riparian natural community and managed wetland. The loss is expected to occur during the first 10 years of Alternative 1B implementation.

- **CM4 Tidal Natural Communities Restoration:** Tidal habitat restoration site preparation and inundation would result in the conversion of an estimated loss of 3,066 acres of modeled Modesto song sparrow habitat by the late long-term timeframe.

- **CM5 Seasonally Inundated Floodplain Restoration:** Construction of setback levees to restore seasonally inundated floodplain would permanently and temporarily remove approximately 80 acres of modeled Modesto song sparrow habitat (44 permanent, 36 temporary). These losses would be expected to occur along the San Joaquin River and other major waterways in CZ 7. The BDCP is expected to restore approximately 5,000 acres of valley/foothill riparian natural community. These lands would be managed as a mosaic of seral stages, age classes, and plant heights, some of which would provide suitable nesting habitat for Modesto song sparrow.

- **CM6 Channel Margin Enhancement:** Channel margin habitat enhancement could result in removal of small amounts of valley/foothill riparian habitat along 20 miles of river and sloughs. The extent of this loss cannot be quantified at this time, but the majority of the enhancement activity would occur along waterway margins where riparian habitat stringers exist, including levees and channel banks. The improvements would occur within the study area on sections of the Sacramento, San Joaquin and Mokelumne Rivers, and along Steamboat and Sutter Sloughs. Some of the restored riparian habitat in the channel margin would be expected to support nesting habitat for Modesto song sparrow.

- **CM11 Natural Communities Enhancement and Management:** A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of modeled habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on available habitat and would be expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP.
Habitat management- and enhancement-related activities could affect Modesto song sparrow nests. If the individuals were to nest in the vicinity of a worksite, equipment operation could destroy nests, and noise and visual disturbances could lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would be available to address these adverse effects.

- Operations and Maintenance: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect Modesto song sparrow use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMM1–AMM7 and conservation actions as described below.

- Injury and Direct Mortality: Construction-related activities would not be expected to result in direct mortality of adult or fledged Modesto song sparrow if they were present in the Plan Area, because they would be expected to avoid contact with construction and other equipment. If either species were to nest in the construction area, construction-related activities, including equipment operation, noise and visual disturbances could destroy nests or lead to their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75 would be available to address these adverse effects.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

**Near-Term Timeframe**

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA. The Plan would remove 2,723 acres of modeled habitat (2,518 permanent, 205 temporary) for Modesto song sparrow in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 146 acres), and implementing other conservation measures (CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, and CM5 Seasonally Inundated Floodplain Restoration—2,577 acres). Typical NEPA and CEQA project-level mitigation ratios for those natural communities that would be affected would be 1:1 for restoration/creation and 1:1 protection of habitat. Using these ratios would indicate that 146 acres of suitable habitat should be restored/created and 146 acres should be protected to compensate for the CM1 losses of Modesto song sparrow habitat. The near-term effects of other conservation actions would remove 2,577 acres of modeled habitat, and therefore require 2,577 acres of restoration/creation and 2,577 acres of protection of Modesto song sparrow habitat using the same typical NEPA and CEQA ratios (1:1 for restoration/creation and 1:1 for protection).

The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of the valley/foothill riparian natural community, restoring 8,850 acres of tidal freshwater emergent wetland, restoring 500 acres of managed wetland, and restoring 400 acres of nontidal marsh in the

Bay Delta Conservation Plan
Draft EIR/EIS 12-1211 November 2013
ICF 00674.11
Plan Area (Table 3-4 in Chapter 3). These conservation actions are associated with CM3, CM4, CM7, and CM10 and would occur in the same timeframe as the construction and early restoration losses, thereby avoiding adverse effects of habitat loss on Modesto song sparrow.

The majority of the riparian restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, Conservation Strategy) and would provide suitable Modesto song sparrow nesting habitat. The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The nontidal marsh restoration would occur in CZs 2, 4, and/or 5, and the managed wetland restoration would occur in CZs 3, 4, 5, or 6. Both the nontidal marsh and managed wetland restoration are associated with CM10 and would provide nesting habitat for Modesto song sparrow.

The Plan also includes commitments to protect patches of important wildlife habitat on cultivated lands such as trees and shrubs along borders and roadside, riparian corridors, and wetlands (Objective CLNC1.3). In addition, 20- to 30-foot-wide hedgerows would be established along field borders and roadsides, which would provide additional habitat for the species (Objective SH2.2). The management of protected grasslands to increase insect prey through techniques such as the avoidance of use of pesticides (Objectives ASWNC2.4, VPNC2.5, and GNC2.4) would provide further benefits to foraging Modesto song sparrows. These Plan objectives represent performance standards for considering the effectiveness of conservation actions. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the typical mitigation that would be applied to the project-level effects of CM1 on Modesto song sparrow, as well as mitigate the near-term effects of the other conservation measures.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.

Modesto song sparrow is not a covered species under the BDCP. For the BDCP avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would be available to address this adverse effect.

Late Long-Term Timeframe

Alternative 1B as a whole would result in the permanent loss of and temporary effects on 3,568 acres (3,327 acres of permanent loss, 241 acres of temporary loss) of modeled Modesto song sparrow habitat during the term of the Plan. The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes conservation commitments through CM3 Natural Communities Protection and Restoration, CM4 Tidal Natural Communities Restoration, and CM10 Nontidal Marsh Restoration to protect 750 acres and restore 5,000 acres of the valley/foothill riparian natural community, restore 24,000 acres of tidal freshwater emergent wetland, restore 500 acres of managed wetland, and restore 1,200 acres of nontidal marsh in the
Plan Area (Table 3-4 in Chapter 3). Additional acres of valley/foothill riparian habitat would be
restored as a component of channel margin enhancement actions (CM6) along 20 miles of river and
slough channels in the Delta, some of which would be expected to support nesting habitat for
Modesto song sparrow. Of the 5,000 acres of restored riparian natural communities, a minimum of
3,000 acres of valley/foothill riparian would be restored within the seasonally inundated floodplain,
and 1,000 acres would be managed as dense early to mid-successional riparian forest (Objectives
VFRNC1.1 and VFRNC1.2). Goals and objectives in the Plan for riparian restoration also include the
maintenance and enhancement of structural heterogeneity (Objective VFRNC2.1) which would
provide suitable nesting habitat for Modesto song sparrow.

The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective
TFEWNC1.1) and would be restored in a way that creates topographic heterogeneity and in areas
that increase connectivity among protected lands (Objective TFEWNC2.2). The nontidal marsh
restoration would occur in CZs 2, 4, and/or 5, and the managed wetland restoration would occur in
CZs 3, 4, 5, or 6. Both the nontidal marsh and managed wetland restoration are associated with
CM10 and would provide nesting habitat for Modesto song sparrow.

The Plan includes commitments to protect patches of important wildlife habitat on cultivated lands
such as trees and shrubs along borders and roadside, riparian corridors, and wetlands (Objective
CLNC1.3). In addition, 20- to 30-foot-wide hedgerows would be established along field borders and
roadsides, which would provide additional habitat for the species (Objective SH2.2). The
management of protected grasslands to increase insect prey through techniques such as the
avoidance of use of pesticides (Objectives ASWNC2.4, VPNC2.5, and GNC2.4) would provide further
benefits to foraging Modesto song sparrows. These Plan objectives represent performance
standards for considering the effectiveness of conservation actions. The acres of restoration and
protection contained in the near-term Plan goals and the additional detail in the biological objectives
satisfy the typical mitigation that would be applied to the project-level effects of CM1 on Modesto
song sparrow, as well as mitigate the near-term effects of the other conservation measures.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2
Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention
Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and
Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged
Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or
minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are
described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures. Modesto song
sparrow is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on
individuals, preconstruction surveys for noncovered avian species would be required to ensure that
nests are detected and avoided. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird
Surveys and Avoid Disturbance of Nesting Birds, would be available to address this adverse effect.

**NEPA Effects:** The loss of Modesto song sparrow habitat and potential for mortality of this special-
status species under Alternative 1B would represent an adverse effect in the absence of other
conservation actions. However, with habitat protection and restoration associated with CM3, CM4,
CM6, CM7, and CM11, guided by biological goals and objectives and by AMM1–AMM7, which would
be in place throughout the construction period, the effects of habitat loss on Modesto song sparrow
under Alternative 1B would not be adverse. The Modesto song sparrow is not a covered species
under the BDCP, and the potential for mortality would be an adverse effect without preconstruction
surveys to ensure that nests are detected and avoided. Mitigation Measure BIO-75 would be available to address this adverse effect.

**CEQA Conclusion:**

**Near-Term Timeframe**

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. The Plan would remove 2,723 acres of modeled habitat (2,518 permanent, 205 temporary) for Modesto song sparrow in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 146 acres), and implementing other conservation measures (CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, and CM5 Seasonally Inundated Floodplain Restoration—2,577 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities that would be affected would be 1:1 for restoration/creation and 1:1 protection of habitat. Using these ratios would indicate that 146 acres of suitable habitat should be restored/created and 146 acres should be protected to compensate for the CM1 losses of Modesto song sparrow habitat. The near-term effects of other conservation actions would remove 2,577 acres of modeled habitat, and therefore require 2,577 acres of restoration/creation and 2,577 acres of protection of Modesto song sparrow habitat using the same typical NEPA and CEQA ratios (1:1 for restoration/creation and 1:1 for protection).

The BDCP has committed to near-term goals of protecting 750 acres and restoring 800 acres of the valley/foothill riparian natural community, restoring 8,850 acres of tidal freshwater emergent wetland, restoring 500 acres of managed wetland, and restoring 400 acres of nontidal marsh in the Plan Area (Table 3-4 in Chapter 3). These conservation actions are associated with CM3, CM4, CM7, and CM10 and would occur in the same timeframe as the construction and early restoration losses, thereby avoiding a significant impact of habitat loss on Modesto song sparrow.

The majority of the riparian restoration acres would occur in CZ 7 as part of a reserve system with extensive wide bands or large patches of valley/foothill riparian natural community (Objectives VFRNC1.1 and VFRNC1.2 in BDCP Chapter 3, Conservation Strategy) and would provide suitable Modesto song sparrow nesting habitat. The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The nontidal marsh restoration would occur in CZs2, 4, and/or 5, and the managed wetland restoration would occur in CZs 3, 4, 5, or 6. Both the nontidal marsh and managed wetland restoration are associated with CM10 and would provide nesting habitat for Modesto song sparrow.

The Plan also includes commitments to protect patches of important wildlife habitat on cultivated lands such as trees and shrubs along borders and roadside, riparian corridors, and wetlands (Objective CLNC1.3). In addition, 20- to 30-foot-wide hedgerows would be established along field borders and roadsides, which would provide additional habitat for the species (Objective SH2.2). The management of protected grasslands to increase insect prey through techniques such as the avoidance of use of pesticides (Objectives ASWNC2.4, VPNC2.5, and GNC2.4) would provide further benefits to foraging Modesto song sparrows. These Plan objectives represent performance
standards for considering the effectiveness of conservation actions. The acres of restoration and
protection contained in the near-term Plan goals and the additional detail in the biological objectives
satisfy the typical mitigation that would be applied to the project-level effects of CM1 on Modesto
song sparrow, as well as mitigate the near-term effects of the other conservation measures.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2
Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention
Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and
Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged
Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or
minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are
described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures. Modesto song
sparrow is not a covered species under the BDCP. For the BDCP to have a less-than-significant
impact on individuals, preconstruction surveys for noncovered avian species would be required to
ensure that nests were detected and avoided. Mitigation Measure BIO-75, Conduct Preconstruction
Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would reduce this impact to a less-than-
significant level.

Late Long-Term Timeframe

Alternative 1B as a whole would result in the permanent loss of and temporary effects on 3,658
acres (3,327 acres of permanent loss, 241 acres of temporary loss) of modeled Modesto song
sparrow habitat during the term of the Plan. The locations of these losses are described above in the
analyses of individual conservation measures. The Plan includes conservation commitments
through CM3 Natural Communities Protection and Restoration, CM4 Tidal Natural Communities
Restoration, and CM10 Nontidal Marsh Restoration to protect 750 acres and restore 5,000 acres of
the valley/foothill riparian natural community, restore 24,000 acres of tidal freshwater emergent
wetland, restore 500 acres of managed wetland, and restore 1,200 acres of nontidal marsh in the
Plan Area (Table 3-4 in Chapter 3). Additional acres of valley/foothill riparian habitat would be
restored as a component of channel margin enhancement actions (CM6) along 20 miles of river and
slough channels in the Delta, some of which would be expected to support nesting habitat for
Modesto song sparrow. Of the 5,000 acres of restored riparian natural communities, a minimum of
3,000 acres of valley/foothill riparian would be restored within the seasonally inundated floodplain,
and 1,000 acres would be managed as dense early to mid-successional riparian forest (Objectives
VFRNC1.1 and VFRNC1.2). Goals and objectives in the Plan for riparian restoration also include the
maintenance and enhancement of structural heterogeneity (Objective VFRNC2.1) which would
provide suitable nesting habitat for Modesto song sparrow.

The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective
TFEWNC1.1) and would be restored in a way that creates topographic heterogeneity and in areas
that increase connectivity among protected lands (Objective TFEWNC2.2). The nontidal marsh
restoration would occur in CZs 2, 4, and/or 5, and the managed wetland restoration would occur in
CZs 3, 4, 5, or 6. Both the nontidal marsh and managed wetland restoration are associated with
CM10 and would provide nesting habitat for Modesto song sparrow.

The Plan includes commitments to protect patches of important wildlife habitat on cultivated lands
such as trees and shrubs along borders and roadside, riparian corridors, and wetlands (Objective
CLNC1.3). In addition, 20- to 30-foot-wide hedgerows would be established along field borders and
roadsides, which would provide additional habitat for the species (Objective SH2.2). The
management of protected grasslands to increase insect prey through techniques such as the
avoidance of use of pesticides (Objectives ASWNC2.4, VPNC2.5, and GNC2.4) would provide further
benefits to foraging Modesto song sparrows. These Plan objectives represent performance
standards for considering the effectiveness of conservation actions. The acres of restoration and
protection contained in the near-term Plan goals and the additional detail in the biological objectives
satisfy the typical mitigation that would be applied to the project-level effects of CM1 on Modesto
song sparrow, as well as mitigate the near-term effects of the other conservation measures.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2
Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention
Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and
Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged
Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or
minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are
described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures. Modesto song
sparrow is not a covered species under the BDCP. For the BDCP to minimize direct mortality of
individuals, preconstruction surveys for noncovered avian species would be required to ensure that
nests are detected and avoided. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird
Surveys and Avoid Disturbance of Nesting Birds, would reduce this impact to a less-than-significant
level.

Considering Alternative 1B’s protection and restoration provisions, which would provide acreages
of new high-value or enhanced habitat in amounts suitable to compensate for habitats lost to
construction and restoration activities, and with the implementation of AMM1–AMM7 and
Mitigation Measure BIO-75, the loss of habitat or direct mortality through implementation of
Alternative 1B would not result in a substantial adverse effect through habitat modifications and
would not substantially reduce the number or restrict the range of Modesto song sparrow.
Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-
significant impact on Modesto song sparrow.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid
Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-143: Effects on Modesto Song Sparrow Associated with Electrical Transmission
Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in
injury or mortality of Modesto song sparrow. Existing lines currently pose this risk for Modesto song
sparrow and the incremental increased risk from the construction of new transmission lines is not
expected to adversely affect the population.

NEPA Effects: The incremental increased risk of bird-powerline strikes from the construction of new
transmission lines would not adversely affect the Modesto song sparrow population.

CEQA Conclusion: The incremental increased risk of bird-powerline strikes from the construction of
new transmission lines would have a less-than-significant impact on the Modesto song sparrow
Impact BIO-144: Indirect Effects of Plan Implementation on Modesto Song Sparrow

Indirect construction-related effects: Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect Modesto song sparrow use of modeled habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5.J, Attachment 5.J.D, Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane, Table 4), although there are no available data to determine the extent to which these noise levels could affect Modesto song sparrow. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect these species or their prey in the surrounding habitat. AMM1–AMM7, including AMM2 Construction Best Management Practices and Monitoring, would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to Modesto song sparrow could also have a negative effect on these species. AMM1–AMM7 would ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

Methylmercury Exposure: Marsh (tidal and nontidal) and floodplain restoration have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury (see BDCP Chapter 3, Conservation Strategy, for details of restoration). Species sensitivity to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community and floodplain restoration could indirectly affect Modesto song sparrow, via uptake in lower tropic levels (as described in the BDCP, Appendix 5.D, Contaminants). In addition, the potential mobilization or creation of methylmercury within the Plan Area varies with site-specific conditions and would need to be assessed at the project level. CM12 Methylmercury Management contains provisions for project-specific Mercury Management Plans. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would be available to address the uncertainty of methylmercury levels in restored tidal marsh and potential impacts on Modesto song sparrow.

NEPA Effects: Indirect effects on Modesto song sparrow as a result of constructing the Alternative 1C water conveyance facilities could adversely affect individuals in the absence of other conservation actions. The incorporation of AMM1–AMM7 into the BDCP and the implementation of Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would minimize this adverse effect. The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of Modesto song sparrow to methylmercury. However, it is unknown what concentrations of methylmercury are harmful to the species and the potential for increased exposure varies substantially within the study area. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 Methylmercury Management would
address the potential impacts of methylmercury levels in restored tidal marsh in the study area. The
site-specific planning phase of marsh restoration would be the appropriate place to assess the
potential for risk of methylmercury exposure for Modesto song sparrow, once site specific sampling
and other information could be developed.

CEQA Conclusion: Indirect effects on Modesto song sparrow as a result of constructing the water
conveyance facilities could have a significant impact on these species. The incorporation of AMM1–
AMM7 into the BDCP and the implementation of Mitigation Measure BIO-75, Conduct
Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would reduce this
impact to a less-than-significant level. The implementation of tidal natural communities restoration
or floodplain restoration could result in increased exposure of Modesto song sparrow to
methylmercury. However, it is unknown what concentrations of methylmercury are harmful to the
species. Site-specific restoration plans that address the creation and mobilization of mercury, as well
as monitoring and adaptive management as described in CM12 Methylmercury Management would
address the potential impacts of methylmercury levels in restored tidal marsh in the study area.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid
Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-145: Periodic Effects of Inundation on Modesto Song Sparrow as a Result of
Implementation of Conservation Components

Flooding of the Yolo Bypass (CM2) would inundate 81-158 acres of modeled Modesto song sparrow
habitat. However, inundation would occur during the nonbreeding season. Reduced foraging habitat
availability would be expected during the fledgling period of the nesting season due to periodic
inundation.

Based on hypothetical floodplain restoration, construction of setback levees from seasonally
inundated floodplain restoration (CM5) could result in periodic inundation of up to approximately
284 acres of Modesto song sparrow modeled habitat (Table 12-1B-52).

The periodic inundation of the Yolo Bypass (CM2) and of seasonal floodplains (CM5) is expected to
restore a more natural flood regime in support of wetland and riparian vegetation types that
support Modesto song sparrow habitat, but may reduce the availability of nesting habitat during
years when flooding extends into the nesting season (after March).

NEPA Effects: Periodic inundation would not result in an adverse effect on Modesto song sparrow
because increased frequency and duration of inundation would be expected to restore a more
natural flood regime in support of wetland and riparian vegetation types that provide Modesto song
sparrow habitat.

CEQA Conclusion: Periodic inundation would have a less-than-significant impact on Modesto song
sparrow because increased frequency and duration of inundation would be expected to restore a
more natural flood regime in support of wetland and riparian vegetation types that provide Modesto
song sparrow habitat.
Bank Swallow

This section describes the effects of Alternative 1B, including construction and implementation of other conservation components, on bank swallow. Bank swallows nest in colonies along rivers, streams, or other water and require fine textured sandy soils in vertical banks to create their burrows. There is little suitable habitat for bank swallow in the study area because most of the erodible banks have been stabilized with levee revetment. The placement of rock revetment prevents the lateral migration of rivers, removing the natural river process that creates vertical banks through erosion (Bank Swallow Technical Advisory Committee 2013, Stillwater Sciences 2007). An estimated 70-90% of the bank swallow population in California nests along the Sacramento and Feather Rivers (Bank Swallow Technical Advisory Committee 2013) upstream of the study area. However, there are three CNDDDB records of bank swallow colonies in the study area: two in CZ 2 north of Fremont Weir, and one in CZ 5 on Brannan Island, just west of Twitchell Island. Construction and restoration associated with Alternative 1B conservation measures would not result in the direct loss of modeled habitat for bank swallow (Table 12-1B-53). However, indirect effects of noise and visual disturbance resulting from CM2 Yolo Bypass Fisheries Enhancement and CM4 Tidal Natural Communities Restoration could impact bank swallow colonies if they were present near work areas. In addition, there is uncertainty with respect to how water flows upstream of the study area would affect bank swallow habitat.

As explained below, impacts on bank swallow would not be adverse for NEPA purposes and would be less than significant for CEQA purposes with the implementation of mitigation measures to monitor colonies and address the uncertainty of upstream operations on the species.

\(^a\) See Appendix 12E for detailed breakdown of conservation measure effects over the BDCP’s near-term and late long-term timeframes.

\(^b\) See discussion below for a description of applicable CMs.

\(^c\) LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

\(^d\) Periodic effects were estimated for the late long-term only.

NT = near-term
LLT = late long-term
NA = not applicable
Impact BIO-146: Indirect Effects of Implementation of Conservation Components on Bank Swallow

Noise and visual disturbances during restoration activities from CM2 Yolo Bypass Fisheries Enhancement, and CM4 Tidal Natural Communities Restoration, including operation of earthmoving equipment and human activities at work sites, could result in temporary disturbances that cause bank swallow to abandon active nest burrows adjacent to construction areas. Bank swallow colonies with occupied burrows have been recorded in CZ 2 and CZ 5, and construction-related disturbances could result in an adverse effect on individuals. Various activities related to CM11 Natural Communities Enhancement and Management could also have indirect impacts on bank swallow.

NEPA Effects: Construction activities associated with habitat restoration could adversely affect bank swallow colonies in the absence of other measures. Noise and visual disturbances could result in adverse effects on bank swallows if active colonies were present within 500 feet of work areas. Mitigation Measure BIO-146, Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized, would be available to address this adverse effect.

CEQA Conclusion: Construction activities associated with habitat restoration could result in a significant impact on bank swallow colonies in the absence of other measures. Noise and visual disturbances could result in significant impacts on bank swallows if active colonies were present within 500 feet of work areas. Implementation of Mitigation Measure BIO-146, Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized, would reduce this impact to a less-than-significant level.

Mitigation Measure BIO-146: Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized

To the extent practicable, BDCP proponents will not construct conservation components during the bank swallow nesting season (April 1 through August 31). If construction activities cannot be avoided during nesting season, a qualified biologist will conduct preconstruction surveys to determine if active bank swallow nesting colonies are present within 500 feet of work areas. If no active nesting colonies are present, no further mitigation is required.

If active colonies are detected, BDCP proponents will establish a nondisturbance buffer (determined in coordination with CDFW and the Bank Swallow Technical Advisory Committee) around the colony during the breeding season. In addition, a qualified biologist will monitor any active colony within 500 feet of construction to ensure that construction activities do not affect nest success.

Impact BIO-147: Effects of Upstream Reservoir and Water Conveyance Facilities Operations on Bank Swallow

Bank swallows are a riparian species that have evolved to deal with a dynamic system that changes with annual variation in variables such as rainfall, or late snowpack runoff. The primary threat to the species is loss of nesting habitat from the placement of rock revetment for levee stabilization.

Because of this limited available habitat, and the reduction of natural river process, the species is highly sensitive to 1) reductions in winter flows which are necessary to erode banks for habitat creation, and 2) high flows during the breeding season. The potential impacts of changes in upstream flows during the breeding season on bank swallows are the flooding of active burrows and destruction of burrows from increased bank sloughing. Bank swallows arrive in California and begin...
to excavate their burrows in March, and the peak egg-laying occurs during April and May (Bank Swallow Technical Advisory Committee 2013). Therefore, increases in flows after the March when the swallows have nested and layed eggs in the burrows could result in the loss of nests. On the Sacramento River, breeding season flows between 14,000 and 30,000 cfs have been associated with localized bank collapses that resulted in partial or complete colony failure (Stillwater Sciences 2007).

The CALSIM II modeling results of mean monthly flow were analyzed for three flow gauge stations on the Sacramento (Sacramento River at Keswick, Sacramento River upstream of Red Bluff, Sacramento River at Verona) and two flow gauge stations on the Feather River (Feather River high-flow channel at Thermalito Dam, and Feather River at the confluence with the Sacramento River). Flows were estimated for wet years, above normal years, below normal years, dry years, and critical years. An average also was estimated (see Chapter 5, Section 5.3.1, Methods for Analysis, for a description of the model). Alternative 1B would implement Operational Scenario A, which is the same Operational Scenario as Alternative 1A described below.

On the Sacramento River, at the Keswick and Red Bluff gauges, mean monthly flows under Alternative 1A would increase between April and August in all but wet years at the Keswick flow gauge (Table 1 in Section 11C.1.1 of Appendix 11C, CALSIM II Model Results Utilized in the Fish Analysis) and in dry and critical years at the gauge upstream of Red Bluff (Table 3 in Section 11C.1.1 of Appendix 11C, CALSIM II Model Results Utilized in the Fish Analysis) which could lead to inundation of active colonies. However, the flows under Existing Conditions and the predicted flows in the late long-term without the project (NAA) also show increases in flows during the breeding season (April through August) in these water year types. Similar trends are shown for the Feather River (Table 15 in Section 11C.1.1 and Table 17 in Section 11C.1.1 of Appendix 11C, CALSIM II Model Results Utilized in the Fish Analysis). In addition, at the Verona gauge on the Sacramento River in average, above normal, and wet water years, flows are predicted to be greater than 14,000 cfs during some months of the breeding season, which could lead to bank collapse events (Tables 1, 3, and 7 in Section 11C.1.1 of Appendix 11C, CALSIM II Model Results Utilized in the Fish Analysis). However, flows of this height are recorded under Existing Conditions at this flow gauge and are also predicted for the late long-term time without the project (NAA).

**NEPA Effects:** High spring flows on the Sacramento and Feather Rivers may already be impacting bank swallow colonies during the breeding season, and predicted flows under Alternative 1B would not be substantially greater than under the No Action Alternative. However, because of the complexity of variables that dictate suitable habitat for the species, there is uncertainty regarding the potential for and magnitude of upstream impacts on bank swallow from changes in water facilities operations. Soil type, high winter flows, and low spring flows all contribute to successful nesting of bank swallow, and even moderate changes in seasonal flows could have an adverse effect on breeding success for the species. Mitigation Measure BIO-147, Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area, would be available to address the uncertainty of potential adverse effects of upstream operations on bank swallow.

**CEQA Conclusion:** High spring flows on the Sacramento and Feather Rivers may already be impacting bank swallow colonies during the breeding season, and predicted flows under Alternative 1B would not be substantially greater than under the No Action Alternative. However, because of the complexity of variables that dictate suitable habitat for the species, there is uncertainty regarding the potential for and magnitude of impacts on bank swallow from changes in upstream operations. There are many variables that dictate suitable habitat for the species that cannot be clearly
Alternative 1B
Terrestrial Biological Resources

quantified, and seasonal changes in flow could increase or decrease suitable habitat for bank swallow depending on soil type and location of current colonies. Implementation of Mitigation Measure BIO-147, *Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area*, would address this potential significant impact and further determine if additional mitigation is required for bank swallow.

**Mitigation Measure BIO-147: Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area**

To address the uncertainty of the impact of upstream spring flows on existing bank swallow habitat, DWR will monitor existing colonies upstream of the study area and collect habitat suitability data including soil type, number of active burrows per colony, and height of average burrows. In addition, to determine the degree to which reduced winter flows are contributing to habitat loss, DWR will quantify the winter flows required for river meander to create suitable habitat through lateral channel migration and bank resurfacing. If impacts of upstream flows on bank swallow are identified, further mitigation may be required after consultation with CDFW and the Bank Swallow Technical Advisory Committee. Recommended mitigation for changes in flow regimes associated with water conveyance includes conservation easements on currently occupied habitat or revetment removal projects to create habitat for bank swallow (Bank Swallow Technical Advisory Committee 2013).

**Yellow-Headed Blackbird**

This section describes the effects of Alternative 1B, including water conveyance facilities construction and implementation of other conservation components, on yellow-headed blackbird. The habitat model used to assess impacts on yellow-headed blackbird includes nesting habitat and foraging habitat. Modeled nesting habitat includes tidal freshwater emergent wetland, other natural seasonal wetland, nontidal freshwater perennial emergent wetland, and managed wetland. Modeled foraging habitat for yellow-headed blackbird consists of cultivated lands and noncultivated land cover types known to support abundant insect populations, including corn, pasture, and feedlots.

Construction and restoration associated with Alternative 1B conservation measures would result in both temporary and permanent losses of yellow-headed blackbird modeled habitat as indicated in Table 12-1B-54. Full implementation of Alternative 1B would include the following biological objectives over the term of the BDCP which would also benefit yellow-headed blackbird (BDCP Chapter 3, *Conservation Strategy*).

- Restore or create at least 24,000 acres of tidal freshwater emergent wetland in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1, associated with CM4).
- Create at least 1,200 acres of nontidal marsh consisting of a mosaic of nontidal perennial aquatic and nontidal freshwater emergent wetland natural communities (Objective NFEW/NPANC1.1, associated with CM10).
- Protect and enhance at least 8,100 acres of managed wetland, at least 1,500 acres of which are in the Grizzly Island Marsh Complex (Objective MWNC1.1, associated with CM3).
- Protect at least 8,000 acres of grassland with at least 2,000 acres protected in CZ 1, at least 1,000 acres protected in CZ 8, at least 2,000 acres protected in CZ 11, and the remainder distributed among CZs 1, 2, 4, 5, 7, 8, and 11 (Objective GNC1.1, associated with CM3).
- Restore at least 2,000 acres of grasslands (Objective GNC1.2, associated with CM8).
• Protect at least 150 acres of alkali seasonal wetland and at least 600 acres of existing vernal pool complex in CZs 1, 8, and/or 11 (Objective ASWNC1.1, Objective VPNC1.1, associated with CM3).

• Maintain and protect the small patches of important wildlife habitats associated with cultivated lands that occur in cultivated lands within the reserve system, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Objective CLNC1.3, associated with CM3).

• Protect at least 11,050 acres of high- to very high-value breeding-foraging habitat (Table 12-1B-38) in CZs 1, 2, 3, 4, 7, 8, or 11 (Objective TRBL1.3, associated with CM3).

• Maintain and protect the small patches of important wildlife habitats associated with cultivated lands that occur in cultivated lands within the reserve system, including isolated valley oak trees, trees and shrubs along field borders and roadsides, remnant groves, riparian corridors, water conveyance channels, grasslands, ponds, and wetlands (Objective CLNC1.3, associated with CM3).

• Increase prey abundance and accessibility for grassland-foraging species (Objective GNC2.4, associated with CM11).

As explained below, with the restoration or protection of these amounts of habitat, in addition to management activities to enhance habitats for the species and implementation of AMM1–AMM7, AMM27 Selenium Management, and Mitigation Measure BIO-75, impacts on yellow-headed blackbird would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Impact BIO-148: Loss of Habitat for and Direct Mortality of Yellow-Headed Blackbird

Alternative 1B conservation measures would result in the combined permanent and temporary loss of up to 49,126 acres of modeled habitat (14,002 acres of nesting habitat and 35,124 acres of foraging habitat) for yellow-headed blackbird (Table 12-1B-54). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass improvements (CM2), tidal habitat restoration (CM4), floodplain restoration (CM5), riparian restoration (CM7), grassland restoration (CM8), marsh restoration (CM10), and construction of conservation hatcheries (CM18). Habitat enhancement and management activities (CM11) which include ground disturbance or removal of nonnative vegetation could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate yellow-headed blackbird suitable habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA effects, and a CEQA conclusion follow the individual conservation measure discussions.

- **CM1 Water Facilities and Operation**: Construction of Alternative 1B water conveyance facilities would result in the combined permanent and temporary loss of up to 54 acres of yellow-headed blackbird nesting habitat (19 acres of permanent loss and 35 acres of temporary loss). In addition, 7,546 acres of foraging habitat would be removed (2,964 acres of permanent loss,
Terrestrial Biological Resources

4,582 acres of temporary loss) (Table 12-1B-54). Impacts from CM1 would occur in the central delta in CZ 4, CZ 5, CZ 6, CZ 7, and CZ 8. There are no occurrences of yellow-headed blackbird that overlap with the construction footprint for CM1. However, Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would require preconstruction surveys and the establishment of no-disturbance buffers and would be available to address potential effects on yellow-headed blackbirds if they were to nest in or adjacent to construction activities. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 1B construction locations.

- **CM2 Yolo Bypass Fisheries Enhancement**: Construction of the Yolo bypass fisheries enhancement would result in the combined permanent and temporary loss of up to 100 acres of nesting habitat (55 acres of permanent loss, 45 acres of temporary loss) in the Yolo Bypass in CZ 2. In addition, 1,144 acres of foraging habitat would be removed (879 acres of permanent loss, 265 acres of temporary loss). The loss is expected to occur during the first 10 years of Alternative 1B implementation.

- **CM4 Tidal Natural Communities Restoration**: Site preparation and inundation from CM4 would permanently remove or convert an estimated 13,847 acres of nesting habitat, which would consist primarily of managed wetland. In addition, 20,029 acres of foraging habitat would be lost or converted as a result of tidal restoration, over half of which would be from the loss or conversion of alfalfa. However, the resulting 65,000 acres of tidal natural communities would also provide habitat for the species, 24,000 acres of which would be tidal freshwater natural communities providing breeding habitat for yellow-headed blackbird.

- **CM5 Seasonally Inundated Floodplain Restoration**: Construction of setback levees to restore seasonally inundated floodplain and riparian restoration actions would remove approximately 2 acres of yellow-headed blackbird nesting habitat (1 acres of permanent loss, 1 acres of temporary loss) and 1,641 acres of foraging habitat (1,051 acres of permanent loss, 590 acres of temporary loss). These losses would be expected after the first 10 years of Alternative 1B implementation along the San Joaquin River and other major waterways in CZ 7.

- **CM7 Riparian Natural Community Restoration**: Riparian restoration would permanently remove approximately 509 acres of yellow-headed blackbird foraging habitat as part of tidal restoration and 2,033 acres as part of seasonal floodplain restoration through CM7.

- **CM8 Grassland Natural Community Restoration**: Restoration of grassland is expected to be implemented on agricultural lands and would result in the conversion of 926 acres of yellow-headed blackbird agricultural foraging habitat to grassland foraging habitat in CZs 1, 2, 4, 5, 7, 8, and 11. If agricultural lands supporting higher value foraging habitat than the restored grassland were removed, there would be a loss of white-tailed kite foraging habitat value. CM8 would result in the restoration of 2,000 acres of grassland foraging habitat in the study area.

- **CM10 Nontidal Marsh Restoration**: Restoration and creation of nontidal freshwater marsh (CM10) would result in the permanent conversion of 988 acres of cultivated lands foraging habitat to nontidal marsh in CZ 2 and CZ 4. Yellow-headed blackbird nesting habitat may develop along the margins of restored nontidal marsh and restoration would also provide foraging habitat for the species.

- **CM11 Natural Communities Enhancement and Management**: Habitat management- and enhancement-related activities could disturb yellow-headed blackbird nests if they were present near work sites. A variety of habitat management actions included in CM11 that are
Alternative 1B

Terrestrial Biological Resources

designed to enhance wildlife values in BDCP-protected habitats may result in localized ground
disturbances that could temporarily remove small amounts of yellow-headed blackbird habitat
and reduce the functions of habitat until restoration is complete. Ground-disturbing activities,
such as removal of nonnative vegetation and road and other infrastructure maintenance, would
be expected to have minor effects on available yellow-headed blackbird habitat. These effects
cannot be quantified, but are expected to be minimal and would be avoided and minimized by
AMM1–AMM7. CM11 would also include the construction of recreational-related facilities
including trails, interpretive signs, and picnic tables (BDCP Chapter 4, Covered Activities and
Associated Federal Actions). The construction of trailhead facilities, signs, staging areas, picnic
areas, bathrooms, etc. would be placed on existing, disturbed areas when and where possible.
However, approximately 50 acres of grassland foraging habitat would be lost from the
construction of trails and facilities.

- **CM18 Conservation Hatcheries**: Implementation of CM18 would remove up to 35 acres of high-
yellow-headed blackbird foraging habitat for the development of a delta and longfin smelt
conservation hatchery in CZ 1. The loss is expected to occur during the first 10 years of Plan
implementation.

- **Operations and Maintenance**: Postconstruction operation and maintenance of the above-ground
water conveyance facilities and restoration infrastructure could result in ongoing but periodic
disturbances that could affect yellow-headed blackbird use of the surrounding habitat.
Maintenance activities would include vegetation management, levee and structure repair, and
re-grading of roads and permanent work areas. These effects, however, would be reduced by
AMMs and conservation actions as described below.

- **Injury and Direct Mortality**: Construction-related activities would not be expected to result in
direct mortality of adult or fledged yellow-headed blackbird if they were present in the Plan
Area, because they would be expected to avoid contact with construction and other equipment.
If yellow-headed blackbird were to nest in the construction area, construction-related activities,
including equipment operation, noise and visual disturbances could destroy nests or lead to
their abandonment, resulting in mortality of eggs and nestlings. Mitigation Measure BIO-75,
*Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be
available to address these adverse effects on yellow-headed blackbird.

The following paragraphs summarize the combined effects discussed above and describe other
BDCP conservation actions that offset or avoid these effects. NEPA and CEQA conclusions are also
included.

**Near-Term Timeframe**

Because the water conveyance facilities construction (CM1) is being evaluated at the project level,
the near-term BDCP conservation strategy has been evaluated to determine whether it would
provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the
effects of construction would not be adverse under NEPA. The Plan would remove 5,913 acres
(5,833 acres of permanent loss, 80 acres of temporary loss) of yellow-headed blackbird nesting
habitat in the study area in the near-term. These effects would result from the construction of the
water conveyance facilities (CM1, 54 acres), and implementing other conservation measures (CM2
*Yolo Bypass Fisheries Enhancement*, CM4 *Tidal Natural Communities Restoration*, and CM5 *Seasonally
Inundated Floodplain Restoration*—5,859 acres). In addition, 13,534 acres of yellow-headed
blackbird foraging habitat would be removed or converted in the near-term (CM1, 7,546 acres; CM2
Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, CM5 Seasonally Inundated Floodplain Restoration, CM7 Riparian Natural Community Restoration, CM8 Grassland Natural Community Restoration, CM10 Nontidal Marsh Restoration, and CM18 Conservation Hatcheries—5,988 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 would be 1:1 for restoration/creation and 1:1 protection of nesting habitat, and 1:1 protection of foraging habitat. Using these ratios would indicate that 54 acres of nesting habitat should be restored/created and 54 acres should be protected to compensate for the CM1 losses of yellow-headed blackbird nesting habitat. In addition, 7,546 acres of foraging habitat should be protected to compensate for the CM1 losses of yellow-headed blackbird foraging habitat. The near-term effects of other conservation actions would require 5,859 acres each of restoration and protection of breeding habitat and 5,988 acres of protection of foraging habitat using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection of nesting and 1: protection of foraging habitat).

The BDCP has committed to near-term goals of restoring 8,850 acres of tidal freshwater emergent wetland, protecting 4,800 acres of managed wetland, protecting 25 acres and restoring 900 acres of nontidal marsh, protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,600 acres of cultivated lands in the Plan Area (Table 3-4 in Chapter 3). These conservation actions are associated with CM3, CM4, CM8, and CM10 and would occur in the same timeframe as the construction and early restoration losses.

The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1 in BDCP Chapter 3, Conservation Strategy) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The 4,800 acres of managed wetland would be protected and enhanced in CZ 11 and would benefit yellow-headed blackbird through the enhancement of degraded areas (such as areas of bare ground or marsh where the predominant vegetation consists of invasive species such as perennial pepperweed) to vegetation such as pickleweed-alkali heath-American bulrush plant associations (Objective MWNC1.1). In addition, at least 900 acres of nontidal marsh would be created, some of which would provide nesting habitat for the species.

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide grassland foraging habitat for yellow-headed blackbird. Insect prey availability and abundance would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Within the cultivated lands, important wildlife habitat such as grasslands, ponds, and wetlands would also be protected and maintained as part of the cultivated lands reserve system which would provide additional habitat for yellow-headed blackbird (Objective CLNC1.3).

At least 15,400 acres of cultivated lands that provide habitat for covered and other native wildlife species would be protected in the near-term time period (Objective CLNC1.1), much of which would provide foraging habitat for yellow-headed blackbird. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the
The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures. The yellow-headed blackbird is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would be available to address this adverse effect.

Late Long-Term Timeframe

The study area supports approximately 82,005 acres of modeled nesting habitat and 333,956 acres of modeled foraging habitat for yellow-headed blackbird. Alternative 1B as a whole would result in the permanent loss of and temporary effects on 13,948 acres of potential nesting habitat (17% of the potential nesting habitat in the study area) and the loss or conversion of 35,124 acres of foraging habitat (11% of the foraging habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures.

The Plan includes conservation commitments through CM3 Natural Communities Protection and Restoration, CM4 Tidal Natural Communities Restoration, CM8 Grassland Natural Community Restoration, and CM10 Nontidal Marsh Restoration to protect and enhance at least 8,100 acres of managed wetland, restore or create at least 24,000 acres of tidal freshwater emergent wetland, create or restore at least 1,200 acres of nontidal marsh, protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex, and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3).

The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1 in BDCP Chapter 3, Conservation Strategy) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The managed wetland would be protected and enhanced in CZ 11 and would benefit yellow-headed blackbird through the enhancement of degraded areas (such as areas of bare ground or marsh where the predominant vegetation consists of invasive species such as perennial pepperweed) to vegetation such as pickleweed-alkali heath-American bulrush plant associations (Objective MWNC1.1). In addition, at least 1,200 acres of nontidal marsh would be created, some of which would provide nesting habitat for the species.

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide grassland foraging habitat for yellow-headed blackbird. Insect prey availability and abundance would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Foraging opportunities would
also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadides within protected cultivated lands (Objective SWHA2.2). Within the cultivated lands, important wildlife habitat such as grasslands, ponds, and wetlands would also be protected and maintained as part of the cultivated lands reserve system which would provide additional habitat for yellow-headed blackbird (Objective CLNC1.3). Of the 48,625 acres of cultivated lands that would be protected and enhanced by the late long-term time period (Objective CLNC1.1), 26,300 acres would be managed in moderate to high-value crop types for tricolored blackbird (Table 3.3-6 in BDCP Chapter 3). These crop types include pasture, sunflower, alfalfa, and other crop types that would provide high-value foraging habitat for yellow-headed blackbird.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.

The yellow-headed blackbird is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would be available to address this adverse effect.

**NEPA Effects:** The loss of yellow-headed blackbird habitat and potential for direct mortality of this special-status species associated with Alternative 1B would represent an adverse effect in the absence of other conservation actions. However, with habitat protection and restoration associated with CM3, CM4, CM8, CM10, and CM11, guided by biological goals and objectives and by AMM1–AMM7, which would be in place throughout the construction phase, the effects of habitat loss would not be adverse under Alternative 1B. The yellow-headed blackbird is not a covered species under the BDCP. For the BDCP to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would be available to address this adverse effect.

**CEQA Conclusion:**

**Near-Term Timeframe**

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA. The Plan would remove 5,913 acres (5,833 acres of permanent loss, 80 acres of temporary loss) of yellow-headed blackbird nesting habitat in the study area in the near-term. These effects would result from the construction of the water conveyance facilities (CM1, 54 acres), and implementing other conservation measures (CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, and CM5 Seasonally Inundated Floodplain Restoration—5,859 acres). In addition, 13,534 acres of yellow-headed blackbird foraging habitat would be removed or converted in the near-term (CM1, 7,546...
acres; CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, CM5 Seasonally Inundated Floodplain Restoration, CM7 Riparian Natural Community Restoration, CM8 Grassland Natural Community Restoration, CM10 Nontidal Marsh Restoration, and CM18 Conservation Hatcheries—5,988 acres).

Typical NEPA and CEQA project-level mitigation ratios for those natural communities affected by CM1 would be 1:1 for restoration/creation and 1:1 protection of foraging habitat. Using these ratios would indicate that 54 acres of nesting habitat should be restored/created and 54 acres should be protected to compensate for the CM1 losses of yellow-headed blackbird nesting habitat. In addition, 7,546 acres of foraging habitat should be protected to compensate for the CM1 losses of yellow-headed blackbird foraging habitat. The near-term effects of other conservation actions would require 5,859 acres each of restoration and protection of breeding habitat and 5,988 acres of protection of foraging habitat using the same typical NEPA and CEQA ratios (1:1 for restoration and 1:1 for protection of nesting and 1:1 protection of foraging habitat).

The BDCP has committed to near-term goals of restoring 8,850 acres of tidal freshwater emergent wetland, protecting 4,800 acres of managed wetland, protecting 25 acres and restoring 900 acres of nontidal marsh, protecting 2,000 acres and restoring 1,140 acres of grassland natural community, protecting 400 acres of vernal pool complex, protecting 120 acres of alkali seasonal wetland complex, and protecting 15,600 acres of cultivated lands in the Plan Area (Table 3-4 in Chapter 3).

These conservation actions are associated with CM3, CM4, CM8, and CM10 and would occur in the same timeframe as the construction and early restoration losses.

The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1 in BDCP Chapter 3, Conservation Strategy) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The 4,800 acres of managed wetland would be protected and enhanced in CZ 11 and would benefit yellow-headed blackbird through the enhancement of degraded areas (such as areas of bare ground or marsh where the predominant vegetation consists of invasive species such as perennial pepperweed) to vegetation such as pickleweed-alkali heath-American bulrush plant associations (Objective MWNC1.1). In addition, at least 900 acres of nontidal marsh would be created, some of which would provide nesting habitat for the species.

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would provide grassland foraging habitat for yellow-headed blackbird. Insect prey availability and abundance would also be increased on protected lands, enhancing the foraging value of these natural communities (Objectives ASWNC2.4, VPNC2.5, and GNC2.4). Foraging opportunities would also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide hedgerows along field borders and roadsides within protected cultivated lands (Objective SWHA2.2). Within the cultivated lands, important wildlife habitat such as grasslands, ponds, and wetlands would also be protected and maintained as part of the cultivated lands reserve system which would provide additional habitat for yellow-headed blackbird (Objective CLNC1.3).

At least 15,400 acres of cultivated lands that provide habitat for covered and other native wildlife species would be protected in the near-term time period (Objective CLNC1.1), much of which would provide foraging habitat for yellow-headed blackbird. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives satisfy the
typical mitigation that would be applied to the project-level effects of CM1 on yellow-headed blackbird habitat, as well as mitigate the near-term effects of the other conservation measures.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.

The yellow-headed blackbird is not a covered species under the BDCP. For the BDCP and in order to avoid an adverse effect on individuals, preconstruction surveys for noncovered avian species would be required to ensure that nests are detected and avoided. The implementation of Mitigation Measure BIO-75, Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would reduce the potential impact on nesting yellow-headed blackbird to a less-than-significant level.

**Late Long-Term Timeframe**

The study area supports approximately 82,005 acres of modeled nesting habitat and 333,956 acres of modeled foraging habitat for yellow-headed blackbird. Alternative 1B as a whole would result in the permanent loss of and temporary effects on 13,948 acres of potential nesting habitat (17% of the potential nesting habitat in the study area) and the loss or conversion of 35,124 acres of foraging habitat (11% of the foraging habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures.

The Plan includes conservation commitments through CM3 Natural Communities Protection and Restoration, CM4 Tidal Natural Communities Restoration, CM8 Grassland Natural Community Restoration, and CM10 Nontidal Marsh Restoration to protect and enhance at least 8,100 acres of managed wetland, restore or create at least 24,000 acres of tidal freshwater emergent wetland, create or restore at least 1,200 acres of nontidal marsh, protect 8,000 acres and restore 2,000 acres of grassland natural community, protect 600 acres of vernal pool complex, protect 150 acres of alkali seasonal wetland complex, and protect 48,625 acres of cultivated lands that provide suitable habitat for native wildlife species (Table 3-4 in Chapter 3).

The tidal freshwater emergent wetland would be restored in CZs 1, 2, 4, 5, 6, and/or 7 (Objective TFEWNC1.1 in BDCP Chapter 3, Conservation Strategy) and would be restored in a way that creates topographic heterogeneity and in areas that increase connectivity among protected lands (Objective TFEWNC2.2). The managed wetland would be protected and enhanced in CZ 11 and would benefit yellow-headed blackbird through the enhancement of degraded areas (such as areas of bare ground or marsh where the predominant vegetation consists of invasive species such as perennial pepperweed) to vegetation such as pickleweed-alkali heath-American bulrush plant associations (Objective MWNC1.1). In addition, at least 1,200 acres of nontidal marsh would be created, some of which would provide nesting habitat for the species.

Grassland restoration and protection would occur in CZs 1, 2, 4, 5, 7, 8, and 11 (Objectives GNC1.1 and GNC1.2) Grassland protection in CZ 1, 8, and 11 would be associated with vernal pool and alkali seasonal wetland complexes (Objectives ASWNC1.1 and VPNC1.1) and would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would
provide grassland foraging habitat for yellow-headed blackbird. Insect prey availability and
abundance would also be increased on protected lands, enhancing the foraging value of these
natural communities (Objectives A$NC2.4, VPNC2.5, and GNC2.4). Foraging opportunities would
also be improved by enhancing prey populations through the establishment of 20- to 30-foot-wide
hedgerows along field borders and roadsides within protected cultivated lands (Objective
SWHA2.2). Within the cultivated lands, important wildlife habitat such as grasslands, ponds, and
wetlands would also be protected and maintained as part of the cultivated lands reserve system
which would provide additional habitat for yellow-headed blackbird (Objective CLNC1.3). Of the
48,625 acres of cultivated lands that would be protected and enhanced by the late long-term time
period (Objective CLNC1.1), 26,300 acres would be managed in moderate to high-value crop types
for tricolored blackbird (Table 3.3-6 in BDCP Chapter 3). These crop types include pasture,
sunflower, alfalfa, and other crop types that would provide high-value foraging habitat for yellow-
headed blackbird.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2
Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention
Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and
Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged
Material, and AMM7 Barge Operations Plan. All of these AMMs include elements that would avoid or
minimize the risk of affecting individuals and species habitats adjacent to work areas. The AMMs are
described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.

The yellow-headed blackbird is not a covered species under the BDCP. For the BDCP to avoid an
adverse effect on individuals, preconstruction surveys for noncovered avian species would be
required to ensure that nests are detected and avoided. Mitigation Measure BIO-75, Conduct
Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds, would reduce this
impact to a less-than-significant level.

Considering Alternative 1B’s protection and restoration provisions, which would provide acreages
of new or enhanced habitat in amounts necessary to compensate for habitat lost to construction and
restoration activities, and with the implementation of AMM1–AMM7 and Mitigation Measure BIO-
75, the loss of habitat or direct mortality through implementation of Alternative 1B would not result
in a substantial adverse effect through habitat modifications and would not substantially reduce the
number or restrict the range of either species. Therefore, the loss of habitat or potential mortality
under this alternative would have a less-than-significant impact on yellow-headed blackbird.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

See Mitigation Measure BIO-75 under Impact BIO-75.

Impact BIO-149: Effects on Yellow-Headed Blackbird Associated with Electrical Transmission Facilities

New transmission lines would increase the risk for bird-power line strikes, which could result in
injury or mortality of yellow-headed blackbirds. Transmission line poles and towers also provide
perching substrate for raptors, which could result in increased predation pressure on yellow-headed
blackbirds. The existing network of transmission lines in the Plan Area currently poses this risk for
yellow-headed blackbirds, and any incremental risk associated with the new transmission line
corridors would be expected to be low. AMM20 Greater Sandhill Crane would further minimize the
risk for bird-power line strikes with the installation of flight diverters on new and selected existing transmission lines.

**NEPA Effects:** New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of yellow-headed blackbird. Transmission line poles and towers also provide perching substrate for raptors, which could result in increased predation pressure on yellow-headed blackbirds. The existing network of transmission lines in the Plan Area currently poses this risk for yellow-headed blackbirds, and any incremental risk associated with the new transmission line corridors would not be expected to have an adverse effect on yellow-headed blackbirds. *AMM20 Greater Sandhill Crane* would further minimize the risk for bird-power line strikes.

**CEQA Conclusion:** New transmission lines would increase the risk for bird-power line strikes, which could result in injury or mortality of yellow-headed blackbird. Transmission line poles and towers also provide perching substrate for raptors, which could result in increased predation pressure on yellow-headed blackbirds. The existing network of transmission lines in the Plan Area currently poses this risk for yellow-headed blackbirds, and any incremental risk associated with the new transmission line corridors would have a less-than-significant impact on yellow-headed blackbird. *AMM20 Greater Sandhill Crane* would further minimize the risk for bird-power line strikes.

**Impact BIO-150: Indirect Effects of Plan Implementation on Yellow-Headed Blackbird**

**Indirect construction- and operation-related effects:** Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect yellow-headed blackbird use of suitable habitat. Construction noise above background noise levels (greater than 50 dBA) could extend 1,900 to 5,250 feet from the edge of construction activities (BDCP Appendix 5J, Attachment 5J.D, *Indirect Effects of the Construction of the BDCP Conveyance Facility on Sandhill Crane*, Table 4), although there are no available data to determine the extent to which these noise levels could affect yellow-headed blackbird. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect the species in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to yellow-headed blackbird habitat could also have a negative effect on the species. AMM1–AMM7 would ensure that measures are in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

**Methylmercury Exposure:** Covered activities have the potential to exacerbate bioaccumulation of mercury in avian species, including yellow-headed blackbird. Marsh (tidal and nontidal) and floodplain restoration have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Species sensitivity
to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community and floodplain restoration could indirectly affect yellow-headed blackbird, via uptake in lower tropic levels (as described in the BDCP, Appendix 5.D, *Contaminants*).

In addition, the potential mobilization or creation of methylmercury within the Plan Area varies with site-specific conditions and would need to be assessed at the project level. **CM12 Methylmercury Management** includes provisions for project-specific Mercury Management Plans. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would be available to address the uncertainty of methylmercury levels in restored tidal marsh and potential effects on yellow-headed blackbird.

**NEPA Effects:** Noise and visual disturbances from the construction of water conveyance facilities could reduce yellow-headed blackbird use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect yellow-headed blackbird use of the surrounding habitat. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address adverse effects on nesting individuals in addition to AMM1–AMM7. The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of yellow-headed blackbird to methylmercury, in restored tidal areas. However, it is unknown what concentrations of methylmercury are harmful to these species and the potential for increased exposure varies substantially within the study area. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12, would address the uncertainty of methylmercury levels in restored tidal marsh in the study area and better inform potential effects on yellow-headed blackbird. The site-specific planning phase of marsh restoration would be the appropriate place to assess the potential for risk of methylmercury exposure for yellow-headed blackbird, once site specific sampling and other information could be developed.

**CEQA Conclusion:** Noise, the potential for hazardous spills, increased dust and sedimentation, and operations and maintenance of the water conveyance facilities under Alternative 1B would have a less-than-significant impact on yellow-headed blackbird with the implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, and AMM1–AMM7. The implementation of tidal natural communities restoration or floodplain restoration could result in increased exposure of yellow-headed blackbird to methylmercury. However, it is unknown what concentrations of methylmercury are harmful to this species. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12, would better inform potential impacts and address the uncertainty of methylmercury levels in restored tidal marsh in the study area.

**Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds**

See Mitigation Measure BIO-75 under Impact BIO-75.
**Impact BIO-151: Periodic Effects of Inundation of Yellow-Headed Blackbird Nesting Habitat as a Result of Implementation of Conservation Components**

Flooding of the Yolo Bypass (CM2) would inundate 961–2,678 acres of nesting habitat and 368–2,678 acres of foraging habitat (Table 12-1B-54). Based on hypothetical floodplain restoration, construction of setback levees for CM5 Seasonally Inundated Floodplain Restoration could result in periodic inundation of approximately 18 acres of nesting habitat and 2,701 acres of nonbreeding habitat (Table 12-1B-54) resulting in the temporary loss of these habitats. Foraging yellow-headed blackbirds would be expected to move to adjacent suitable foraging habitat when the bypass is inundated, as they do under the current flooding regime. However, this inundation could reduce the availability of nesting habitat during years when flooding extends into the nesting season (past March). The periodic inundation of the Yolo Bypass (CM2) and of other floodplains (CM5) is expected to restore a more natural flood regime in support of wetland and riparian vegetation types that support nesting habitat.

**NEPA Effects:** Implementation of CM2 and CM5 would result in periodic inundation of nesting and foraging habitat for yellow-headed blackbird. Periodic inundation would not have an adverse effect on yellow-headed blackbird because inundation is expected to take place outside of the breeding season, and, although foraging habitat may be temporarily unavailable, birds would be expected to move to adjacent foraging habitat.

**CEQA Conclusion:** Implementation of CM2 and CM5 would result in periodic inundation of nesting and foraging habitat for yellow-headed blackbird. Periodic inundation would have a less-than-significant impact on yellow-headed blackbird because inundation is expected to take place outside of the breeding season, and, although foraging habitat would be temporarily unavailable, birds would be expected to move to adjacent foraging habitat.

**Riparian Brush Rabbit**

The habitat model used to assess effects on the riparian brush rabbit consists of 38 vegetation associations within the valley/foothill riparian natural community and adjacent grasslands. The vegetation associations were selected based on a review of understory and overstory composition from Hickson and Keeler-Wolf (2007) and species habitat requirements.

Just until recently, the only known naturally occurring populations of riparian brush rabbits were confined to Caswell Memorial State Park (MSP), a 258-acre park supporting riparian oak woodland on the Stanislaus River immediately southeast of the study area, and in the south Delta southwest of Lathrop, which is within the study area (Williams and Basey 1986; Williams et al. 2002) (Figure 12-46). On October 11, 2012 a single female riparian brush rabbit was captured near Durham Ferry Road in riparian habitat along the San Joaquin River between Caswell MSP and Lathrop (Bradbury pers. comm.). The is only the 2nd naturally occurring population documented outside of Caswell MSP. Factors considered in assessing the value of adversely affected habitat for riparian brush rabbit, to the extent information was available, included size and degree of isolation of habitat patches, proximity to recorded species occurrences, and adjacency to conserved lands.

Construction and restoration associated with Alternative 1B conservation measures would result in both temporary and permanent losses of riparian brush rabbit modeled habitat as indicated in Table 12-1B-55. Full implementation of Alternative 1B would also include biological objectives over the term of the BDCP to benefit the riparian brush rabbit (BDCP Chapter 3, Conservation Strategy). The conservation strategy for the riparian brush rabbit, with conservation principles involves...
Terrestrial Biological Resources

protecting, restoring or creating, and maintaining habitat and corridors near the largest remaining
fragments of habitat and extant populations; providing high-water refugia from flooding; and
managing feral predators (dogs and cats) in areas occupied by the species. The conservation
measures that would be implemented to achieve the biological goals and objectives are summarized
below.

- Provide a range of elevations in restored floodplains that transition from frequently flooded
  (e.g., every 1 to 2 years) to infrequently flooded (e.g., every 10 years or more) areas to provide a
  range of habitat conditions, upland habitat values, and refugia from flooding during most flood
  events (Objective L1.5, associated with CM3, CM5, and CM8).

- Increase the size and connectivity of the reserve system by acquiring lands adjacent to and
  between existing conservation lands (Objective L1.6, associated with CM3).

- Allow floods to promote fluvial processes, such that bare mineral soils are available for natural
  recolonization of vegetation, desirable natural community vegetation is regenerated, and
  structural diversity is promoted, or implement management actions that mimic those natural
  disturbances (Objective L2.1, associated with CM3, CM5, and CM11).

- Protect and improve habitat linkages that allow terrestrial covered and other native species to
  move between protected habitats within and adjacent to the Plan Area (Objective L3.1, 19
  associated with CM3–CM8, and CM11).

- Restore or create 5,000 acres of valley/foothill riparian natural community, with at least 3,000
  acres occurring on restored seasonally inundated floodplain (Objective VFRNC1.1, associated
  with CM3 and CM7).

- Protect 750 acres of existing valley/foothill riparian natural community in CZ 7 by year 10
  (Objective VFRNC1.2, associated with CM3).

- Maintain 1,000 acres of early- to mid-successional vegetation with a well-developed understory
  of dense shrubs on restored seasonally inundated floodplain (Objective VFRNC2.2, associated
  with CM5, CM7, and CM11).

- Of the 750 acres of protected valley/foothill riparian natural community protected under
  Objective VFRNC1.2, protect at least 200 acres of suitable riparian brush rabbit habitat (defined
  in CM7 Riparian Natural Community Restoration) that is occupied by the species or contiguous
  with occupied habitat (Objective RBR1.1, associated with 3).

- Of the 1,000 acres of early- to midsuccessional riparian habitat maintained under VFRNC2.2,
  maintain at least 800 acres within the range of the riparian brush rabbit (CZ 7), in areas that are
  adjacent to or that facilitate connectivity with occupied or potentially occupied habitat
  (Objective RBR1.2, associated with CM3, CM7, and CM11).

- Of the 5,000 acres of valley/foothill riparian natural community restored under Objective
  VFRNC1.1, restore/create and maintain at least 300 acres of early- to mid-successional riparian
  habitat that meets the ecological requirements of the riparian brush rabbit and that is within or
  adjacent to or that facilitates connectivity with existing occupied or potentially occupied habitat
  (Objective 1.3, associated with CM3, CM7, and CM11).

- Create and maintain high-water refugia in the 300 acres of restored riparian brush rabbit
  habitat and the 200 acres of protected riparian brush rabbit habitat, through the retention,
  construction and/or restoration of high-ground habitat on mounds, berms, or levees, so that
  refugia are no further apart than 66 feet (Objective RBR1.4, associated with CM7 and CM11).
In protected riparian areas that are occupied by riparian brush rabbit, monitor for and control nonnative predators that are known to prey on riparian brush rabbit (Objective RBR1.5, associated with CM11).

Of the 8,000 acres of grasslands protected under Objective GNC1.1 and the 2,000 acres of grasslands restored under Objective GNC1.2, protect or restore grasslands on the landward side of levees adjacent to restored floodplain to provide flood refugia and foraging habitat for riparian brush rabbit (Objective RBR1.6, associated with CM3 and CM8).

As explained below, with the restoration and protection of these amounts of habitat, in addition to implementation of the AMMs to reduce potential effects, impacts on riparian brush rabbit would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

\(^a\) See Appendix 12E for detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

\(^b\) See discussion below for a description of applicable CMs.

\(^c\) LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

\(^d\) Periodic effects were estimated for the late long-term only.

NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-152: Loss or Conversion of Habitat for and Direct Mortality of Riparian Brush Rabbit

Alternative 1B conservation measures would result in the permanent loss of up to 107 acres of riparian habitat and 231 acres of associated grassland habitat for the riparian brush rabbit in the study area (Table 12-1B-55). The hypothetical footprint for levee construction under CM5, overlaps with one occurrence record for riparian brush rabbit, south of the Interstate 5/Interstate 205 interchange. Conservation measures resulting in permanent habitat loss include conveyance facilities construction (CM1), tidal natural communities restoration (CM4), and floodplain restoration (CM5). Each of these individual activities is described below. A summary statement of
the combined impacts and NEPA effects and a CEQA conclusion follow the individual conservation
measure discussions.

- **CM1 Water Facilities and Operation**: Development of Alternative 1B water conveyance facilities
would result in the permanent removal of approximately 5 acres of riparian habitat and
137 acres of associated grassland habitat and in the temporary removal of 5 acres of riparian
habitat and 30 acres of grassland habitat for riparian brush rabbit in CZ 8 (Table 12-1B-55). The
riparian habitat that would be removed is of low value for the riparian brush rabbit as is
consists of several small, isolated patches surrounded by agricultural lands northeast of Clifton
Court Forebay. The associated grasslands are also of low value for the species: They consist of
long linear strips that abut riparian habitat, but extend several miles from the riparian habitat
and, therefore, provide few if any opportunities for adjacent cover. Trapping efforts conducted
for the riparian brush rabbit in this area were negative (BDCP Appendix 3.E, Conservation
Principles for the Riparian Brush Rabbit and Riparian Woodrat). Refer to the Terrestrial Biology
Map Book for a detailed view of Alternative 1B construction locations.

- **CM4 Tidal Natural Communities Restoration**: Tidal habitat restoration site preparation and
inundation would permanently remove approximately 19 acres of riparian habitat and 18 acres
of associated grassland habitat for the riparian brush rabbit in CZ 7 in the late long-term. The
riparian habitat that would be removed consists of relatively small and isolated patches along
canals and irrigation ditches surrounded by agricultural lands in the Union Island and Roberts
Island areas, and several small patches along the San Joaquin River. The habitat that would be
removed is not adjacent to any exiting conserved lands, and is several miles north and northeast
of the northernmost riparian brush rabbit record located northeast of Paradise Cut (Williams et
al. 2002). Although the final footprint for tidal natural communities restoration would differ
from the hypothetical footprint, AMM25 Riparian Woodrat and Riparian Brush Rabbit requires
that tidal natural communities restoration avoid removal of any habitat occupied by the riparian
brush rabbit.

- **CM5 Seasonally Inundated Floodplain Restoration**: Levee construction associated with floodplain
restoration would result in the permanent removal of approximately 43 acres of riparian habitat
and 26 acres of associated grassland habitat for the riparian brush rabbit in CZ 7 in the late
longterm. Levee construction would also result in the temporary removal of 35 acre riparian
habitat and 20 acres of grassland habitat for the riparian brush rabbit. Although the effects are
considered temporary, five years to several decades may be required for ecological succession
to occur and for restored riparian habitat to replace the function of habitat that has been
affected. The value of this habitat for riparian brush rabbit is high: although it consists of small
patches and narrow bands of riparian vegetation, these areas are in proximity to, or contiguous
with, habitat with recorded occurrences of riparian brush rabbit. The hypothetical footprint for
levee construction overlaps with one occurrence record for riparian brush rabbit, south of the
Interstate 5/Interstate 205 interchange.

Although the final floodplain restoration design would differ from the hypothetical footprint
used for this effects analysis, restoration of the river floodplain in CZ 7 would be targeted in the
general area of the riparian brush rabbit population. Implementation of adaptive management
described in AMM25 would ensure that riparian brush rabbit habitat permanently removed
does not exceed maximum allowable habitat loss for this species.

- **CM11 Natural Communities Enhancement and Management**: A variety of habitat management
actions included in CM11 that are designed to enhance wildlife values in BDCP protected
habitats may result in localized ground disturbances that could temporarily remove small amounts of riparian brush rabbit habitat. Enhancement and management actions in riparian brush rabbit habitat within the reserve system may include invasive plant removal, planting and maintaining vegetation to improve and sustain habitat characteristics for the species, and creating and maintaining flood refugia. These activities are expected to have minor adverse effects on available riparian brush rabbit habitat and are expected to result in overall improvements to and maintenance of riparian brush rabbit habitat values over the term of the BDCP. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized through the AMMs listed below.

Passive recreation in the reserve system could result in disturbance of individual riparian brush rabbits foraging in the ecotone between riparian and adjacent open habitats. However, AMM37, *Recreation* limits trail development adjacent to riparian corridors within the range of the riparian brush rabbit. With this minimization measure in place, recreation related effects on the riparian brush rabbit are expected to be minimal.

- Operations and maintenance: Ongoing maintenance of BDCP facilities are not expected to adversely affect the riparian brush rabbit because the species is not expected to occur in the vicinity of proposed facilities.
- Injury and direct mortality: Water conveyance facility construction is not likely to result in injury or mortality of individual riparian brush rabbits because the species is not likely to be present in the areas that would be affected by this activity, based on live trapping results (BDCP Appendix 3.E, *Conservation Principles for the Riparian Brush Rabbit and Riparian Woodrat*). Tidal natural communities restoration would not result in injury or mortality of the riparian brush rabbit because tidal natural communities restoration projects would be designed to avoid occupied riparian brush rabbit habitat and, if that is not possible, rabbits would be trapped and relocated as described in AMM25 (see BDCP Appendix 3.C, *Avoidance and Minimization Measures*). Activities associated with construction of setback levees for floodplain restoration could result in injury or mortality of riparian brush rabbits: however, preconstruction surveys, construction monitoring, and other measures would be implemented to avoid and minimize injury or mortality of this species during construction (AMM25).

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA effects and a CEQA conclusion are also included.

**Near-Term Timeframe**

Because the water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would not be adverse under NEPA.

Alternative 1B would result in permanent and temporary effects combined on 10 acres of riparian habitat and 167 acres of grassland habitat for riparian brush rabbit in the near-term as a result of construction of the water conveyance facilities (CM1). The habitat would be lost in the valley/foothill riparian and grassland natural communities. All the near-term loss of riparian brush rabbit habitat would occur in an area unlikely to be occupied by the species. Habitat loss in CZ 7, in areas known or likely to be occupied, would occur during the early long-term and late long-term...
timeframes. Riparian restoration would be phased to minimize temporal habitat loss. There would be no near-term losses from CM2–CM18.

Typical NEPA project-level mitigation ratios for these natural communities that would be affected and that are identified in the biological goals and objectives for riparian brush rabbit in Chapter 3 of the BDCP would be 1:1 for restoration and 1:1 for protection of the valley/foothill riparian natural community, and 2:1 for protection of grassland. Using these ratios would indicate that 10 acres of riparian habitat should be restored, 10 acres of riparian habitat should be protected, and 334 acres of grassland should be protected for riparian brush rabbit for near-term losses.

The BDCP has committed to near-term restoration of 800 acres of riparian (Objective VFRNC1.1 and an unknown number of associated acres of grassland and protection of 750 acres of riparian (Objective VFRNC1.2) with an unknown number of associated acres of grassland (Table 3-4 in Chapter 3). In addition, the species-specific biological goals and objectives (RBR1.1–RBR1.6) would inform the near-term protection and restoration efforts. The natural community restoration and protection activities are expected to be concluded during the first 10 years of plan implementation, which is close enough in time to the occurrence of impacts to constitute adequate mitigation for NEPA purposes. These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 1B would be not be adverse under NEPA, because the number of acres required to meet the typical ratios described above would be only 10 acres of riparian habitat restored, 10 acres of riparian habitat protected, and 334 acres of grassland protected.

The plan also contains commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, AMM7 Barge Operations Plan, AMM10 Restoration of Temporarily Affected Natural Communities, AMM25 Riparian Woodrat and Riparian Brush Rabbit, and AMM37 Recreation. These AMMs contain elements that avoid or minimize the risk of BDCP activities affecting habitats and species adjacent to work areas and storage sites. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.

Late Long-Term Timeframe

There are 6,012 acres of modeled riparian brush rabbit habitat in the Plan Area, consisting of 2,909 acres of riparian habitat and 3,103 acres of associated grassland habitat. Alternative 1Ba whole would result in permanent and temporary effects combined on 107 acres of modeled riparian habitat and 231 acres of modeled grassland habitat for riparian brush rabbit, representing 4% and 8% of the riparian and grassland modeled habitat in CZ 6, CZ 7, and CZ 8. Habitat lost in CZ 6 and CZ 8 is fragmented, isolated, and unlikely to support the species. Habitat would also be lost in areas in CZ 7 that provide high-value habitat for the species.

The BDCP would restore at least 5,000 acres and protect at least 750 acres of valley/foothill riparian natural community, a portion of which is expected to consist of suitable riparian brush rabbit habitat (Objectives VFRNC1.1 and VFRNC1.2). Objective RBR1.2 requires that at least 800 acres of early- to midsuccessional riparian natural community be conserved in CZ 7, in areas that are adjacent to or that facilitate connectivity with existing occupied or potentially occupied habitat. This would consist of 200 acres of protected habitat (Objective RBR1.1) and 600 acres of restored habitat. The 800 acres to be conserved would consist of early successional riparian vegetation suitable for riparian brush rabbit. The conserved habitat would also be part of a larger, more
contiguous, and less patchy area of protected and restored riparian natural community than what
currently exists in CZ 7 and would be contiguous with existing modeled riparian brush rabbit
habitat. The species-specific objectives further require that the 200 acres of protected riparian
habitat (Objective RBR1.4) and at least 300 acres of the restored riparian habitat (Objective RBR1.3)
meet more specific ecological requirements of riparian brush rabbit, including large patches of
dense riparian brush; ecotonal edges that transition from brush species to grasses and forbs,
scaffolding plants to support vines that grow above flood levels; a tree canopy that is open, if
present; and high-ground refugia from flooding. In protected riparian areas that are occupied by
riparian brush rabbit, nonnative predators that are known to prey on riparian brush rabbit would
be monitored and controlled (Objective RBR1.5).

In addition to restoration and protection of riparian habitat for the riparian brush rabbit, the Plan
would protect, and, if necessary, create or restore grasslands adjacent to suitable riparian vegetation
in areas outside the floodplain levees (Objective RBR1.6). These grasslands are expected to provide
additional foraging opportunities for the riparian brush rabbit and upland refugia during flood
events. The actual acreage of grassland to be restored or protected for riparian brush rabbit would
depend on site-specific needs adjacent to restored and protected riparian habitat (CM3). Grasslands
on the landward side of levees adjacent to restored floodplain would be restored or protected as
needed to provide flood refugia and foraging habitat for riparian brush rabbit (Objective RBR1.6).

In addition to grasslands protected and restored outside the levees for riparian brush rabbit as
needed, the floodplains would transition from areas that flood frequently (e.g., every 1 to 2 years) to
areas that flood infrequently (e.g., every 10 years or more) (Objective L1.5): these infrequently
flooded areas would provide refuge for the riparian brush rabbit during most years. The BDCP
would also create and maintain mounds, levee sections, or other high areas in restored and
protected riparian areas (Objective RBR1.4) that are designed specifically to provide flood refugia
for the riparian brush rabbit (Appendix 3.F, Conservation Principles for the Riparian Brush Rabbit and
Riparian Woodrat). Additionally, nonnative predators that are known to prey on riparian brush
rabbit (e.g., feral dogs and cats) would be monitored in protected and restored riparian areas that
are occupied by riparian brush rabbit (Objective RBR1.5), and controlled as needed (CM11).

The BDCP’s beneficial effects analysis (BDCP Chapter 5, Section 5.6, Effects on Covered Wildlife and
Plant Species) estimates that the restoration and protection actions discussed above, as well as the
restoration of valley/foothill riparian and grassland that could overlap with the species model,
would result in the restoration of 800 acres of riparian and 79 acres of grassland modeled habitat
for riparian brush rabbit. In addition, protection of valley/foothill riparian and grassland could
overlap with the species model and would result in the protection of 200 acres of riparian and 317
acres of grassland riparian brush rabbit modeled habitat.

NEPA Effects: In the near-term, the loss of riparian brush rabbit habitat under Alternative 1B would
not be adverse because there is little likelihood of riparian brush rabbits being present and the
BDCP has committed to protecting and restoring the acreage required to meet the typical mitigation
ratios described above. In the late long-term, the losses of riparian brush rabbit riparian and
grassland habitat associated with Alternative 1B, in the absence of other conservation actions,
would represent an adverse effect as a result of habitat modification and potential direct mortality
of a special-status species. However, with habitat protection and restoration associated with the
conservation components, guided by landscape-scale goals and objectives and by AMM1–AMM6,
AMM10, AMM25, and AMM37, the effects of Alternative 1B as a whole on riparian brush rabbit
would not be adverse.
**CEQA Conclusion:**

**Near-Term Timeframe**

Because the water conveyance facilities construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the effects of construction would be less than significant under CEQA.

Alternative 1B would result in permanent and temporary effects combined on 10 acres of riparian habitat and 167 acres of grassland habitat for riparian brush rabbit in the near-term as a result of construction of the water conveyance facilities (CM1). The habitat would be lost in the valley/foothill riparian and grassland natural communities. All the near-term loss of riparian brush rabbit habitat would occur in an area unlikely to be occupied by the species. Habitat loss in CZ 7, in areas known or likely to be occupied, would occur during the early long-term and late long-term timeframes. Riparian restoration would be phased to minimize temporal habitat loss. There would be no near-term losses from CM2–CM18.

Typical NEPA project-level mitigation ratios for these natural communities that would be affected and that are identified in the biological goals and objectives for riparian brush rabbit in Chapter 3 of the BDCP would be 1:1 for restoration and 1:1 for protection of the valley/foothill riparian natural community, and 2:1 for protection of grassland. Using these ratios would indicate that 10 acres of riparian habitat should be restored, 10 acres of riparian habitat should be protected, and 334 acres of grassland should be protected for riparian brush rabbit for near-term losses.

The BDCP has committed to near-term restoration of 800 acres of riparian (Objective VFRNC1.1) and an unknown number of associated acres of grassland and protection of 750 acres of riparian (Objective VFRNC1.2) with an unknown number of associated acres of grassland (Table 3-4 in Chapter 3). In addition, the species-specific biological goals and objectives (RBR1.1–RBR1.6) would inform the near-term protection and restoration efforts. The natural community restoration and protection activities are expected to be concluded during the first 10 years of plan implementation, which is close enough in time to the occurrence of impacts to constitute adequate mitigation for CEQA purposes. These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 1B would be less than significant under CEQA, because the number of acres required to meet the typical ratios described above would be only 10 acres of riparian habitat protected, 10 acres of riparian habitat restored, and 334 acres of grassland habitat protected.

The plan also contains commitments to implement AMM1–AMM7, AMM10, AMM25, and AMM37. These AMMs contain elements that avoid or minimize the risk of BDCP activities affecting habitats and species adjacent to work areas and storage sites. The AMMs are described in detail in BDCP Appendix 3.C, *Avoidance and Minimization Measures*.

**Late Long-Term Timeframe**

There are 6,012 acres of modeled riparian brush rabbit habitat in the Plan Area, consisting of 2,909 acres of riparian habitat and 3,103 acres of associated grassland habitat. Alternative 1B would result in permanent and temporary effects combined on 105 acres of modeled riparian habitat and 244 acres of modeled grassland habitat for riparian brush rabbit in CZ 6, CZ 7, and CZ 8. Habitat lost in CZ 6 and CZ 8 is fragmented, isolated, and unlikely to support the species. Habitat would also be lost in areas in CZ 7 that provide high-value habitat for the species.
The BDCP would restore at least 5,000 acres and protect at least 750 acres of valley/foothill riparian natural community, a portion of which is expected to consist of suitable riparian brush rabbit habitat (Objectives VFRNC1.1 and VFRNC1.2). Objective RBR1.2 requires that at least 800 acres of early- to mid-successional riparian natural community be conserved in CZ 7, in areas that are adjacent to or that facilitate connectivity with existing occupied or potentially occupied habitat. This would consist of 200 acres of protected habitat (Objective RBR1.1) and 600 acres of restored habitat. The 800 acres to be conserved would consist of early successional riparian vegetation suitable for riparian brush rabbit. The conserved habitat would also be part of a larger, more contiguous, and less patchy area of protected and restored riparian natural community than what currently exists in CZ 7 and would be contiguous with existing modeled riparian brush rabbit habitat. The species-specific objectives further require that the 200 acres of protected riparian habitat (Objective RBR1.4) and at least 300 acres of the restored riparian habitat (Objective RBR1.3) meet more specific ecological requirements of riparian brush rabbit, including large patches of dense riparian brush; ecotonal edges that transition from brush species to grasses and forbs, scaffolding plants to support vines that grow above flood levels; a tree canopy that is open, if present; and high-ground refugia from flooding. In protected riparian areas that are occupied by riparian brush rabbit, nonnative predators that are known to prey on riparian brush rabbit would be monitored and controlled (RBR1.5).

In addition to restoration and protection of riparian habitat for the riparian brush rabbit, the BDCP would protect, and, if necessary, create or restore grasslands adjacent to suitable riparian vegetation in areas outside the floodplain levees (Objective RBR1.6). These grasslands are expected to provide additional foraging opportunities for the riparian brush rabbit and upland refugia during flood events. The actual acreage of grassland to be restored or protected for riparian brush rabbit would depend on site-specific needs adjacent to restored and protected riparian habitat (CM3). Grasslands on the landward side of levees adjacent to restored floodplain would be restored or protected as needed to provide flood refugia and foraging habitat for riparian brush rabbit (Objective RBR1.6).

In addition to grasslands protected and restored outside the levees for riparian brush rabbit as needed, the floodplains would transition from areas that flood frequently (e.g., every 1 to 2 years) to areas that flood infrequently (e.g., every 10 years or more) (Objective L1.5); these infrequently flooded areas would provide refuge for the riparian brush rabbit during most years. The BDCP would also create and maintain mounds, levee sections, or other high areas in restored and protected riparian areas (Objective RBR1.4) that are designed specifically to provide flood refugia for the riparian brush rabbit (Appendix 3.F, Conservation Principles for the Riparian Brush Rabbit and Riparian Woodrat). Additionally, nonnative predators that are known to prey on riparian brush rabbit (e.g., feral dogs and cats) would be monitored in protected and restored riparian areas that are occupied by riparian brush rabbit (Objective RBR1.5), and controlled as needed (CM11).

The BDCP’s beneficial effects analysis (BDCP Chapter 5, Section 5.6, Effects on Covered Wildlife and Plant Species) estimates that the restoration and protection actions discussed above, as well as the restoration of valley/foothill riparian and grassland that could overlap with the species model, would result in the restoration of 800 acres of riparian and 79 acres of grassland modeled habitat for riparian brush rabbit. In addition, protection of valley/foothill riparian and grassland could overlap with the species model and would result in the protection of 200 acres of riparian and 317 acres of grassland riparian brush rabbit modeled habitat.

Only a small proportion of the habitat losses would be considered occupied and of high value. The Alternative 1B conservation measures provide for large acreages of riparian brush rabbit riparian
and grassland habitats to be protected and restored, and the BDCP includes AMM1–AMM7, AMM10, AMM25, and AMM37, which are directed at minimizing or avoiding potential effects during construction and operation of the conservation measures. Overall, the BDCP would provide a substantial net benefit to the riparian brush rabbit through the increase in available habitat and habitat in protected status. These protected areas would be managed and monitored to support the species.

Considering the habitat restoration and protection associated with CM3, CM7, CM8 and CM11, guided by species-specific goals and objectives and by AMM1–AMM7, AMM10, AMM25, and AMM37, the temporary and permanent losses of riparian and grassland habitat and potential for direct mortality of riparian brush rabbit as a result of implementing Alternative 1B would not represent a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. The loss of habitat and potential mortality of riparian brush rabbits would not be a significant impact under CEQA.

Impact BIO-153: Indirect Effects of Plan Implementation on Riparian Brush Rabbit

Noise and visual disturbance adjacent to construction activities could indirectly affect the use of modeled riparian brush rabbit riparian habitat and associated grassland habitat in the study area. These construction activities would include water conveyance construction, tidal natural communities restoration construction, construction and subsequent maintenance of transmission lines, and construction of setback levees. Construction would occur in CZ 8 where there is suitable habitat for the species but surveys by ESRP did not indicate the species is present in this area; therefore, the potential for adverse noise and visual effects from conveyance facility construction would be minimal. Tidal natural communities restoration construction would potentially affect adjacent riparian habitat and associated grassland habitat for this species: however, adverse effects on the species are unlikely because tidal natural communities restoration projects would be sited to avoid areas occupied by riparian brush rabbit. The activity most likely to result in noise and visual disturbance to riparian brush rabbit is the construction of setback levees for floodplain restoration, which would take place in CZ 7, where the species is known to occur. The use of mechanical equipment during construction might cause the accidental release of petroleum or other contaminants that would affect the riparian brush rabbit in adjacent habitat, if the species is present.

NEPA Effects: Implementation of the AMMs listed above as part of implementing BDCP Alternative 1B would avoid the potential for substantial adverse effects on riparian brush rabbits, either indirectly or through habitat modifications or result in a substantial reduction in numbers or a restriction in the range of riparian brush rabbits. Therefore, indirect effects of Alternative 1B would not have an adverse effect on riparian brush rabbit.

CEQA Conclusion: Indirect effects from conservation measure operations and maintenance as well as construction-related noise and visual disturbances could affect riparian brush rabbit in riparian and grassland habitats. The use of mechanical equipment during construction could cause the accidental release of petroleum or other contaminants that could affect riparian brush rabbit. The inadvertent discharge of sediment or excessive dust adjacent to riparian brush rabbit habitat could also have a negative effect on the species. With implementation of AMM1–AMM7, AMM10, AMM25, and AMM37 as part of Alternative 1B, the BDCP would avoid the potential for substantial adverse effects on riparian brush rabbits, either indirectly or through habitat modifications and would not result in a substantial reduction in numbers or a restriction in the range of riparian brush rabbits. Indirect effects of Alternative 1B would have a less-than-significant impact on riparian brush rabbit.
Impact BIO-154: Periodic Effects of Inundation of Riparian Brush Rabbit Habitat as a Result of Implementation of Conservation Components

**CM5 Seasonally Inundated Floodplain Restoration** is the only covered activity expected to result in periodic inundation of riparian brush rabbit habitat. This activity would periodically inundate approximately 264 acres of riparian habitat (9% of riparian habitat in the Plan Area) and 423 acres of associated grassland habitat (14% of associated grassland habitat in the Plan Area) for the riparian brush rabbit. The area between existing levees that would be breached and the newly constructed setback levees would be inundated through seasonal flooding. The potentially inundated areas consist of high-value habitat for the species: although they consist of small patches and narrow bands of riparian vegetation, many of these areas are in proximity to, or contiguous with, habitat with recorded occurrences of riparian brush rabbit. The restored floodplain would include a range of elevations from lower lying areas that flood frequently (e.g., every 1 to 2 years) to higher elevation areas that flood infrequently (e.g., every 10 years or more).

Seasonal flooding in restored floodplains can result in injury or mortality of individuals if riparian brush rabbits occupy these areas and cannot escape flood waters. One recorded occurrence of riparian brush rabbit (Williams et al. 2002), just west of Stewart Road in Mossdale, is in the area that would be seasonally flooded based on the hypothetical restoration footprint.

**NEPA Effects:** Floodplain restoration under CM5 would periodically affect only a small proportion of the modeled riparian brush rabbit habitat in the study area. The adverse effects of periodic inundation on the riparian brush rabbit would be minimized through construction and maintenance of flood refugia to allow riparian brush rabbits to escape inundation. Therefore, implementing Alternative 1B, including AMM1–AMM7, AMM10, AMM25, and AMM37, would not be expected to result in substantial adverse effects on riparian brush rabbit, either directly or through habitat modifications and would not result in a substantial reduction in numbers or a restriction in the range of riparian brush rabbits. Therefore, Alternative 1B would not adversely affect the species.

**CEQA Conclusion:** Floodplain restoration under CM5 would periodically affect only a small proportion of the modeled riparian brush rabbit habitat in the study area. The overall effect of seasonal inundation on existing riparian natural communities may instead be beneficial. Historically, flooding was the main natural disturbance regulating ecological processes in riparian areas, and flooding promotes the germination and establishment of many native riparian plants. In the late long-term, seasonal inundation in areas currently occupied by riparian vegetation may contribute to the establishment of high-value habitat for covered riparian species, such as the riparian brush rabbit. Long-term management of riparian areas would ensure that refugia also exist along the edges of seasonally inundated habitat.

The adverse effects of periodic inundation on the riparian brush rabbit would be minimized through construction and maintenance of flood refugia to allow riparian brush rabbits to escape inundation. Therefore, implementing Alternative 1B, including AMM1–AMM7, AMM10, AMM25, and AMM37, would not be expected to result in substantial adverse effects on riparian brush rabbit, either directly or through habitat modifications and would not result in a substantial reduction in numbers or a restriction in the range of riparian brush rabbits. Periodic inundation of riparian and grassland habitat for riparian brush rabbit under Alternative 1B would have a less-than-significant impact on the species.
Riparian Woodrat

The habitat model used to assess effects for the riparian woodrat consists of selected plant alliances from the valley/foothill riparian natural community, geographically constrained to the south Delta portion of the BDCP area in CZ 7, south of SR 4 and Old River Pipeline along the Stanislaus, San Joaquin, Old, and Middle Rivers. Valley/foothill riparian areas along smaller drainages (Paradise Cut, Tom Paine Slough), and some larger streams in the northern portion of CZ 7 were excluded from the riparian woodrat habitat model due to a lack of trees or riparian corridors that were too narrow. Factors considered in assessing the value of affected habitat for the riparian woodrat, to the extent that information is available, include habitat patch size and connectivity.

The riparian woodrat is not known to occur in the study area. The only verified extant population of riparian woodrats rangewide is 2 miles east of the southern end of the study area in Caswell Memorial State Park along the Stanislaus River (Williams and Basey 1986:1–112; 1993). Riparian woodrat may occur in small patches of valley oak riparian forest along the San Joaquin River from the southern tip of the study area north to approximately the Interstate 5 overcrossing near Lathrop. Construction and restoration associated with Alternative 1B conservation measures would result in both temporary and permanent losses of riparian woodrat modeled habitat as indicated in Table 12-1B-56. Tidal habitat restoration, floodplain restoration, and protection and management of natural communities could affect modeled riparian woodrat habitat. However, because the species is not known to occur in the study area it is not expected to be affected by BDCP actions unless the species were to establish in the study area over the term of the BDCP. Full implementation of Alternative 1B would also include biological objectives over the term of the BDCP to benefit the riparian woodrat (BDCP Chapter 3, Conservation Strategy). The conservation strategy for the riparian woodrat involves providing opportunities for population expansion into the Plan Area from adjacent lands to the south and southeast. The strategy focuses on restoring and maintaining suitable habitat at the southernmost end of CZ 7, providing connectivity with existing populations to the south and southeast, and creating and maintaining flood refugia. This conservation approach is consistent with the recovery plan (U.S. Fish and Wildlife Service 1998) and conservation principles (BDCP, Appendix 3.E). The conservation measures that would be implemented to achieve the biological goals and objectives are summarized below.

- Provide a range of elevations in restored floodplains that transition from frequently flooded (e.g., every 1 to 2 years) to infrequently flooded (e.g., every 10 years or more) areas to provide a range of habitat conditions, upland habitat values, and refugia from flooding during most flood events (Objective L1.5, associated with CM3, CM5, and CM8).
- Increase the size and connectivity of the reserve system by acquiring lands adjacent to and between existing conservation lands (Objective L1.6, associated with CM3).
- Protect and improve habitat linkages that allow terrestrial covered and other native species to move between protected habitats within and adjacent to the Plan Area (Objective L3.1, associated with CM3-CM8, and CM11).
- Restore or create 5,000 acres of valley/foothill riparian natural community, with 3,000 acres occurring on restored seasonally inundated floodplain (Objective VFRNC1.1, associated with CM3 and CM7).
- Protect 750 acres of existing valley/foothill riparian natural community in CZ 7 by year 10 (Objective VFRNC1.2, associated with CM3).
• Restore, maintain and enhance structural heterogeneity with adequate vertical and horizontal overlap among vegetation components and over adjacent riverine channels, freshwater emergent wetlands, and grasslands (Objective VFRNC2.1, associated with CM5, CM7, and CM11).

• Of the 5,000 acres of valley/foothill riparian natural community restored under Objective VFRNC1.1, restore/create and maintain 300 acres riparian habitat in CZ 7 that meets the ecological requirements of the riparian woodrat (i.e., dense willow understory and oak overstory) and that is adjacent to or facilitates connectivity with existing occupied or potentially occupied habitat (Objective RW1.1, associated with CM3, CM7, CM11).

• Provide and maintain high-water refugia in the 300 acres of riparian woodrat habitat restored under Objective RW1.1 through the retention, construction, and/or restoration of high-ground habitat on mounds, berms, or levees, so that refugia are no further apart than 67 feet (Objective RW1.2, associated with CM7 and CM11).

As explained below, with the restoration and protection of these amounts of habitat, in addition to implementation of the AMMs to reduce potential effects, impacts on riparian woodrat would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

Impact BIO-155: Loss or Conversion of Habitat for and Direct Mortality of Riparian Woodrat

• Alternative 1B conservation measures would result in the permanent loss of up to 51 acres of habitat (2% of the habitat in the study area) and temporary loss of up to 34 acres of habitat for riparian woodrat (Table 12-1B-56). Construction of Alternative 1B water conveyance facilities (CM1), tidal natural communities restoration (CM4) and seasonally inundated floodplain restoration (CM5) would remove habitat. Each of these individual activities is described below.

A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow
Alternative 1B

Terrestrial Biological Resources

the individual conservation measure discussions **CM1 Water Facilities and Operation**: Development of Alternative 1B water conveyance facilities would result in the temporary removal of approximately 1 acre of modeled habitat for riparian woodrat in CZ 8 (Table 12-1B-56). The modeled habitat that would be removed is of low value for the riparian woodrat as is consists of several small, isolated patches surrounded by agricultural lands northeast of Clifton Court Forebay. Trapping efforts conducted for the riparian woodrat in this area were negative (BDCP Appendix 3.E, *Conservation Principles for the Riparian Brush Rabbit and Riparian Woodrat*). Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 1B construction locations.

- **CM4 Tidal Natural Communities Restoration**: Tidal habitat restoration site preparation and inundation would permanently remove approximately 10 acres of modeled habitat for the riparian woodrat in CZ 7. This habitat is of low value, consisting of a small, isolated patch surrounded by agricultural lands, and the species has a relatively low likelihood of being present in these areas. The measures described in AMM25 *Riparian Woodrat and Riparian Brush Rabbit* require that tidal natural communities restoration avoid removal of any habitat occupied by the riparian woodrat as determined by presence/absence surveys. Because the estimates of habitat loss due to tidal inundation are based on projections of where restoration may occur, actual habitat loss is expected to be lower because sites would be selected to minimize effects on riparian woodrat.

- **CM5 Seasonally Inundated Floodplain Restoration**: Levee construction associated with floodplain restoration would result in the permanent removal of approximately 41 acres of modeled habitat for the riparian woodrat in CZ 7. The value of this habitat for riparian woodrat is moderate. Although the habitat consists of small patches and narrow bands of riparian vegetation and no riparian woodrats have detected in CZ 7, the riparian patches are in proximity to each other along the San Joaquin River. There are two species occurrences immediately south of CZ 7, one of which is less than 1.5 mile from the southernmost patch of riparian habitat potentially affected by levee construction.

The final floodplain restoration design would differ from the hypothetical footprint used for this effects analysis. However, monitoring and adaptive management described in CM11 and AMM25 would ensure that modeled habitat permanently removed does not exceed the amount estimated based on the hypothetical footprint. Habitat loss is expected to be lower than 41 acres because sites would be selected and restoration designed to minimize effects on the riparian woodrat. If natural flooding is insufficient to maintain appropriate riparian woodrat vegetation structure, the vegetation would be actively managed to provide suitable habitat structure as described in CM11 Natural Communities Enhancement and Management.

Levee construction would also result in the temporary removal of 33 acres of modeled habitat for the riparian woodrat. Although the effects are considered temporary, 5 years to several decades may be required for ecological succession to occur and for restored riparian habitat to replace the function of habitat that has been affected.

- **CM11 Natural Communities Enhancement and Management**: A variety of habitat management actions included in CM11 that are designed to enhance wildlife values in BDCP protected habitats may result in localized ground disturbances that could temporarily remove small amounts of riparian woodrat habitat. Enhancement and management actions in riparian woodrat habitat within the reserve system may include invasive plant removal, planting and maintaining vegetation to improve and sustain habitat characteristics for the species, and
creating and maintaining flood refugia. These activities are expected to have minor adverse
effects on available riparian woodrat habitat and are expected to result in overall improvements
to and maintenance of riparian woodrat habitat values over the term of the BDCP. These effects
cannot be quantified, but are expected to be minimal and would be avoided and minimized
through the AMMs listed below.

- Operations and maintenance: The only ongoing effects on the riparian woodrat are those
potentially resulting from habitat enhancement and management activities. Enhancement and
management actions in riparian woodrat habitat within the reserve system may include invasive
plant removal, planting and maintaining vegetation to improve and sustain habitat
characteristics for the species, and creating and maintaining flood refugia. These activities may
result in harassment of riparian woodrats through noise and visual disturbance which would be
minimized with implementation of AMM1–AMM7, AMM10, and AMM25.

- Injury and direct mortality: Water conveyance facility construction is not likely to result in
injury or mortality of individual riparian woodrats because the species is not likely to be present
in the areas that would be affected by this activity, based on live trapping results (BDCP
Appendix 3.E, Conservation Principles for the Riparian Brush Rabbit and Riparian Woodrat). Tidal
natural communities restoration would not result in injury or mortality of the riparian woodrats
because tidal natural communities restoration projects would be designed to avoid occupied
riparian woodrat habitat and if that is not possible to trap and relocate the species (AMM25).
Activities associated with construction of setback levees for floodplain restoration could result
in injury or mortality of riparian woodrats: however, preconstruction surveys, construction
monitoring, and other measures would be implemented under AMM25 to avoid and minimize
injury or mortality of this species during construction, as described in Appendix 3.C. If occupied
riparian woodrat habitat cannot be avoided, mortality would be avoided through
implementation of a trapping and relocation program. The program would be developed in
coordination with USFWS, and relocation would be to a site approved by USFWS prior to
construction activities.

The following paragraphs summarize the combined effects discussed above and describe other
BDCP conservation actions that offset or avoid these effects. NEPA effects and a CEQA conclusion are
also included.

**Near-Term Timeframe**

Because water conveyance facilities construction is being evaluated at the project level, the near-
term BDCP strategy has been analyzed to determine whether it would provide sufficient habitat
protection or restoration in an appropriate timeframe to ensure that the construction effects would
not be adverse under NEPA. Alternative 1B would result in temporary effects on 1 acre of modeled
habitat for riparian woodrat in the near-term as a result of construction of the water conveyance
facilities (CM1). The habitat would be lost in the valley/foothill riparian. All the near-term loss of
riparian woodrat habitat would result from CM1 conveyance facility construction in CZ 8, and would
occur in an area not likely to be occupied by the species. Habitat loss in CZ 7, in areas known or
likely to be occupied, would occur during the early long-term and late long-term implementation
periods. Riparian restoration would be phased to minimize temporal habitat loss. There would be no
near-term losses from CM2–CM18.

Typical NEPA project-level mitigation ratios for these natural communities that would be affected
and that are identified in the biological goals and objectives for riparian woodrat in Chapter 3 of the
BDCP would be 1:1 for restoration and 1:1 for protection of the valley/foothill riparian natural community. Using these ratios would indicate that 1 acre of riparian habitat should be restored and 1 acre of riparian habitat should be protected for riparian woodrat for near-term losses.

The BDCP has committed to near-term restoration of 800 acres of riparian (Objective VFRNC1.1) and protection of 750 acres of riparian (Objective VFRNC1.2) (Table 3-4 in Chapter 3). In addition, the species-specific biological goals and objectives (RW1.1 and RW1.2) would inform the near-term protection and restoration efforts. The natural community restoration and protection activities are expected to be concluded during the first 10 years of plan implementation, which is close enough in time to the occurrence of impacts to constitute adequate mitigation for NEPA purposes. These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 1B would not be adverse under NEPA, because only 1 acre of modeled habitat would be temporarily affected and there is only limited potential for minor adverse effects on woodrats or its habitat from implementation of CM11.

These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized through the BDCP’s commitment to AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material (RTM), and Dredged Material, AMM7 Barge Operations Plan, AMM10 Restoration of Temporarily Affected Natural Communities, and AMM25 Riparian Woodrat and Riparian Brush Rabbit. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.

Late Long-Term Timeframe

The study area supports approximately 2,166 acres of modeled riparian woodrat habitat. Alternative 1B as a whole would result in the permanent loss of and temporary removal of 85 acres of modeled habitat for riparian woodrat habitat during the late long-term. None of this habitat is considered occupied.

The BDCP would restore at least 5,000 acres and protect at least 750 acres of valley/foothill riparian natural community, a portion of which is expected to consist of suitable riparian brush rabbit habitat (Objectives VFRNC1.1 and VFRNC1.2). Objective RW1.1 requires at least 300 acres of riparian habitat that meets the ecological requirements of the riparian woodrat (e.g., dense willow understory and oak overstory) and that is adjacent to or facilitates connectivity with existing occupied or potentially occupied habitat to be restored in CZ 7. The conserved habitat would also be part of a larger, more contiguous, and less patchy area of protected and restored riparian natural community than what currently exists in CZ 7 and would be contiguous with existing modeled riparian woodrat habitat. The species-specific objective further requires that the 300 acres of restored riparian habitat meet more specific ecological requirements of riparian woodrat (e.g., dense willow understory and oak overstory). Additionally, assuming the protected riparian natural community would provide riparian woodrat habitat proportional to the amount of modeled habitat in this natural community in the Plan Area (12% of the riparian natural community in the Plan Area is modeled riparian woodrat habitat), the protection of 750 acres of riparian natural community (CM3) would provide an estimated 90 acres of protected riparian woodrat habitat that is comparable to or of higher value than existing modeled grassland habitat. All riparian protection would occur during the near-term period, to offset early riparian losses.
The BDCP would also create and maintain mounds, levee sections, or other high areas in restored and protected riparian areas (Objective RW1.2) that are designed specifically to provide flood refugia for the riparian woodrat (Appendix 3.E, Conservation Principles for the Riparian Brush Rabbit and Riparian Woodrat). In addition, the restored floodplains would transition from areas that flood frequently (e.g., every 1 to 2 years) to areas that flood infrequently (e.g., every 10 years or more) (Objective L1.5): these infrequently flooded areas would provide refuge for the riparian woodrat during most years.

The BDCP’s beneficial effects analysis (BDCP Chapter 5, Section 5.6, Effects on Covered Wildlife and Plant Species) estimates that the restoration and protection actions discussed above, as well as the restoration of valley/foothill riparian that could overlap with the species model, would result in the restoration of 300 acres of modeled habitat for riparian woodrat. In addition, protection of valley/foothill riparian could overlap with the species model and would result in the protection of 90 acres riparian woodrat modeled habitat.

Although there are no records of occurrences of the riparian woodrat in the study area, habitat restoration in CZ 7, in the vicinity of occurrences south of the study area, would increase opportunities for northward expansion of the species into the study area Implementation of Alternative 1B conservation measures is not expected to adversely affect the riparian woodrat for the following reasons.

- There are no riparian woodrat occurrences in the Plan Area.
- The habitat that would be removed consists of small patches that are of moderate value for the species.
- The habitat that would be removed permanently is a small proportion of the total habitat in the Plan Area (2%).
- Avoidance and minimization measures would be implemented to avoid injury or mortality of riparian woodrats, and to minimize loss of occupied habitat.
- Floodplain restoration would be designed to provide flood refugia so that flooding would not adversely affect any riparian woodrats that occupy restored floodplains.

**NEPA Effects:** Alternative 1B would provide a substantial benefit to the riparian woodrat through the net increase of available habitat and a net increase of habitat in protected status. These protected areas would be managed and monitored to support the species. The habitat that would be affected by Alternative 1B is currently unoccupied, and habitat removal is not expected to result in a discernible change in the abundance or distribution of riparian woodrats if they occupy study area habitats. Should the species be detected in the study area, implementation of AMM1–AMM7, AMM10, and AMM25 would avoid and minimize the effects of conservation component construction and implementation. Therefore, the loss of habitat and potential mortality of individuals under Alternative 1B would not have an adverse effect on riparian woodrat.

**CEQA Conclusion:**

**Near-Term Timeframe**

Because water conveyance facilities construction is being evaluated at the project level, the near-term BDCP strategy has been analyzed to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the construction effects would be less than significant for CEQA purposes.
Alternative 1B would result in temporary effects on 1 acre of modeled habitat for riparian woodrat in the near-term as a result of construction of the water conveyance facilities (CM1). The habitat would be lost in the valley/foothill riparian. All the near-term loss of riparian woodrat habitat would result from CM1 conveyance facility construction, and would occur in CZ 8 in an area not likely to be occupied by the species. Habitat loss in CZ 7, in areas known or likely to be occupied, would occur during the early long-term and late long-term implementation periods. Riparian restoration would be phased to minimize temporal habitat loss. There would be no near-term losses from CM2–CM18.

Typical CEQA project-level mitigation ratios for these natural communities that would be affected and that are identified in the biological goals and objectives for riparian woodrat in Chapter 3 of the BDCP would be 1:1 for restoration and 1:1 for protection of the valley/foothill riparian natural community. Using these ratios would indicate that 1 acre of riparian habitat should be restored and 1 acre of riparian habitat should be protected for riparian woodrat for near-term losses.

The BDCP has committed to near-term restoration of 800 acres of riparian (Objective VFRNC1.1) and protection of 750 acres of riparian (Objective VFRNC1.2) (Table 3-4 in Chapter 3). In addition, the species-specific biological goals and objectives (RW1.1 and RW1.2) would inform the near-term protection and restoration efforts. The natural community restoration and protection activities are expected to be concluded during the first 10 years of plan implementation, which is close enough in time to the occurrence of impacts to constitute adequate mitigation for CEQA purposes.

These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 1B would not be significant under CEQA, because only 1 acre of modeled habitat would be temporarily affected and there is only limited potential for minor adverse effects on woodrats or its habitat from implementation of CM1.

These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized through the BDCP’s commitment to AMM1–AMM7, AMM10, and AMM25. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.

**Late Long-Term Timeframe**

The study area supports approximately 2,166 acres of modeled riparian woodrat habitat. Alternative 1B as a whole would result in the permanent loss of and temporary removal of 85 acres of modeled habitat for riparian woodrat habitat during the late long-term. None of this habitat is considered occupied.

The BDCP would restore at least 5,000 acres and protect at least 750 acres of valley/foothill riparian natural community, a portion of which is expected to consist of suitable riparian brush rabbit habitat (Objectives VFRNC1.1 and VFRNC1.2). Objective RW1.1 requires at least 300 acres of riparian habitat that meets the ecological requirements of the riparian woodrat (e.g., dense willow understory and oak overstory) and that is adjacent to or facilitates connectivity with existing occupied or potentially occupied habitat to be restored in CZ 7. The conserved habitat would also be part of a larger, more contiguous, and less patchy area of protected and restored riparian natural community than what currently exists in CZ 7 and would be contiguous with existing modeled riparian woodrat habitat. The species-specific objective further requires that the 300 acres of restored riparian habitat meet more specific ecological requirements of riparian woodrat (e.g., dense willow understory and oak overstory). Additionally, assuming the protected riparian natural community would provide riparian woodrat habitat proportional to the amount of modeled habitat in this natural community in the Plan Area (12% of the riparian natural community in the Plan Area...
is modeled riparian woodrat habitat), the protection of 750 acres of riparian natural community
(CM3) would provide an estimated 90 acres of protected riparian woodrat habitat that is
comparable to or of higher value than existing modeled grassland habitat. All riparian protection
would occur during the near-term period, to offset early riparian losses.

The Plan would also create and maintain mounds, levee sections, or other high areas in restored and
protected riparian areas (Objective RW1.2) that are designed specifically to provide flood refugia for
the riparian woodrat (BDCP Appendix 3.E, Conservation Principles for the Riparian Brush Rabbit and
Riparian Woodrat). In addition, the restored floodplains would transition from areas that flood
frequently (e.g., every 1 to 2 years) to areas that flood infrequently (e.g., every 10 years or more)
(Objective L1.5): these infrequently flooded areas would provide refuge for the riparian woodrat
during most years.

The BDCP’s beneficial effects analysis (BDCP Chapter 5, Section 5.6, Effects on Covered Wildlife and
Plant Species) estimates that the restoration and protection actions discussed above, as well as the
restoration of valley/foothill riparian that could overlap with the species model, would result in the
restoration of 300 acres of modeled habitat for riparian woodrat. In addition, protection of
valley/foothill riparian could overlap with the species model and would result in the protection of
90 acres riparian woodrat modeled habitat.

Although there are no records of occurrences of the riparian woodrat in the study area, habitat
restoration in CZ 7, in the vicinity of occurrences south of the study area, would increase
opportunities for northward expansion of the species into the study area Implementation of
Alternative 1B conservation measures is not expected to adversely affect the riparian woodrat for
the following reasons.

- There are no riparian woodrat occurrences in the Plan Area.
- The habitat that would be removed consists of small patches that are of moderate value for the
  species.
- The habitat that would be removed permanently is a small proportion of the total habitat in the
  Plan Area (2%).
- Avoidance and minimization measures would be implemented to avoid injury or mortality of
  riparian woodrats, and to minimize loss of occupied habitat.
- Floodplain restoration would be designed to provide flood refugia so that flooding would not
  adversely affect any riparian woodrats that occupy restored floodplains.

Alternative 1B would provide a substantial benefit to the riparian woodrat through the net increase
of available habitat and a net increase of habitat in protected status. These protected areas would be
managed and monitored to support the species. The habitat that would be affected by Alternative 1B
is currently unoccupied, and habitat removal is not expected to result in a discernible change in the
abundance or distribution of riparian woodrats if they occupy study area habitats. Should the
species be detected in the study area, AMM1–AMM7, AMM10, and AMM25 would avoid and
minimize the effects of conservation component construction and implementation. Therefore, the
loss of habitat and potential mortality of individuals under Alternative 1B would not have a
significant impact on riparian woodrat.
**Impact BIO-156: Indirect Effects of Plan Implementation on Riparian Woodrat**

Noise and visual disturbance adjacent to construction activities could indirectly affect the use of modeled habitat for riparian woodrat. These effects are related construction activities associated with water conveyance construction, tidal natural community restoration construction, and construction of setback levees. Indirect effects on the species from construction associated with tidal natural community restoration are unlikely because tidal natural community restoration projects would be sited to avoid areas occupied by riparian woodrat. The activity most likely to result in noise and visual disturbance to riparian woodrat is the construction of setback levees.

**NEPA Effects:** Implementation of the AMMs listed above as part of implementing BDCP Alternative 1B would avoid the potential for substantial adverse effects on riparian woodrats, either indirectly or through habitat modifications or result in a substantial reduction in numbers or a restriction in the range of riparian woodrats. Therefore, indirect effects of Alternative 1B would not have an adverse effect on riparian woodrat.

**CEQA Conclusion:** Should the species be detected in the study area, indirect effects of conservation measure construction and implementation could impact riparian woodrat and its habitat. AMM1–AMM7, AMM10, and AMM25 would avoid and minimize the impact.

**Impact BIO-157: Periodic Effects of Inundation of Riparian Woodrat Habitat as a Result of Implementation of Conservation Components**

*CM5 Seasonally Inundated Floodplain Restoration* is the only covered activity expected to result in periodic inundation of riparian woodrat habitat. Floodplain restoration would result in periodic inundation of up to 203 acres of riparian woodrat habitat (9% of the riparian woodrat habitat in the Plan Area). The area between existing levees that would be breached and the newly constructed setback levees would be inundated through seasonal flooding. The potentially inundated areas consist of moderate-value habitat for the species. Although the habitat consists of small patches and narrow bands of riparian vegetation and no riparian woodrats have detected in CZ 7, the riparian patches are in proximity to each other along the San Joaquin River and there are two species occurrences immediately south of CZ 7, one of which is less than 1 mile from the southernmost patch of riparian habitat potentially affected by levee construction. The restored floodplains would transition from areas that flood frequently (e.g., every 1 to 2 years) to areas that flood infrequently (e.g., every 10 years or more).

**NEPA Effects:** Alternative 1B’s period inundation of 203 acres of riparian habitat for riparian woodrat is not expected to result in substantial adverse effects on riparian woodrat, either directly or through habitat modifications and would not result in a substantial reduction in numbers or a restriction in the range of riparian woodrat. The effects of periodic inundation on the riparian woodrat would be minimized through construction and maintenance of flood refugia to allow riparian woodrats to escape inundation. Therefore, the periodic inundation of riparian woodrat habitat would not adversely affect the species Alternative 1B.

**CEQA Conclusion:** Floodplain restoration under CM5 would periodically affect a total of 203 acres of riparian habitat for riparian woodrat, representing 9% of the 2,166 acres of modeled riparian woodrat habitat in the study area. The impact of periodic inundation on the riparian woodrat would be minimized through construction and maintenance of flood refugia to allow riparian woodrats to escape inundation, as described in AMM25. Implementation of CM5 would not be expected to result in significant impacts on riparian woodrat, either directly or through habitat modifications, and
would not result in a substantial reduction in numbers or a restriction in the range of riparian woodrats. Periodic inundation of riparian woodrat habitat under Alternative 1B would have a less-than-significant impact.

**Salt Marsh Harvest Mouse**

This section describes the effects of Alternative 1B, including water conveyance facilities construction and implementation of other conservation components, on the salt marsh harvest mouse. The habitat model used to assess effects for the salt marsh harvest mouse includes six habitat types: primary tidal marsh habitat, secondary tidal marsh habitat (low marsh), secondary upland habitat adjacent to tidal marsh habitat, primary habitat within managed wetlands, secondary habitat within managed wetlands (dominated by plants characteristic of low marsh), and upland habitats within managed wetland boundaries. The tidal and managed wetland habitats were discriminated recognizing that regardless of habitat value, managed wetlands are at high risk of catastrophic flooding and have lower long-term conservation value than tidal wetlands.

Construction and restoration associated with Alternative 1B conservation measures would result in effects on modeled salt marsh harvest mouse habitat, which would include permanent losses and habitat conversions (i.e., existing habitat converted to greater or lesser valued habitat for the species post-restoration) as indicated in Table 12-1B-57. All of the effects on the species would take place over an extended period of time as tidal marsh is restored in the Plan Area. Full implementation of Alternative 1B would also include the following conservation actions over the term of the BDCP to benefit salt marsh harvest mouse (BDCP Chapter 3, *Conservation Strategy*).

- Restore or create 6,000 acres of tidal brackish emergent wetland in CZ 11 to be consistent with the final Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California (Objective TBEWNC1.1, associated with CM4).
- Within the 6,000 acres of tidal brackish emergent wetland restored or created, distribute 1,500 acres of middle and high marsh (primary salt marsh harvest mouse habitat) to contribute to total (existing and restored) acreage targets for each complex as specified in the final Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California (Objective TBEWNC1.2, associated with CM4).
- Limit perennial pepperweed to no more than 10% cover in the tidal brackish emergent wetland natural community within the reserve system (Objective TBEWNC2.1).
- Protect and enhance at least at least 1,500 acres of managed wetland in Grizzly Island Marsh Complex for the benefit of salt marsh harvest mouse (Objective MWNC1.1, associated with CM3).
- Protect or restore grasslands adjacent to restored tidal brackish emergent wetlands to provide at least 200 feet of adjacent grasslands beyond the sea level rise accommodation area (Objective GNC1.4, associated with CM3 and CM8).
- Provide viable habitat areas for salt marsh harvest mouse within the 1,500 acres of restored or created middle and high marsh as defined in the final Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California (Objective SMHM1.1).
- Provide viable habitat areas for salt marsh harvest mouse within the 1,500 acres of managed wetland protected and enhanced in the Grizzly Island Marsh Complex as defined in the final
Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California, and increase population levels above the current baseline (Objective SMHM1.2).

As explained below, with the restoration or protection of these amounts of habitat, in addition to implementation of AMMs to minimize potential effects, impacts on the salt marsh harvest mouse would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

\(^a\) See Appendix 12E for detailed breakdown of conservation measure effects over the BDCP’s near-term and late long-term timeframes.

\(^b\) See discussion below for a description of applicable CMs.

\(^c\) LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

\(^d\) Periodic effects were estimated for the late long-term only.

TBEW = tidal brackish emergent wetland

MW = managed wetland

NT = near-term

LLT = late long-term

NA = not applicable

Impact BIO-158: Loss or Conversion of Habitat for and Direct Mortality of Salt Marsh Harvest Mouse

Alternative 1B tidal restoration (CM4) would be the only conservation measure resulting in effects on salt marsh harvest mouse habitat. Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. Each of these activities is described in detail below. A summary statement of the
combined impacts and NEPA and CEQA conclusions follows the individual conservation measure
discussions.

- **CM4 Tidal Natural Communities Restoration** would result in effects on 6,968 acres of salt marsh
  harvest mouse modeled habitat, which would include 5,376 acres of permanent losses and 1,592
  acres of habitat conversions. Salt marsh harvest mouse may be displaced temporarily from areas
  of converted habitat but these areas would ultimately provide suitable habitat for the species.
  However, 1,058 of these acres would be downgraded from primary habitat (67 acres of primary
  tidal brackish emergent wetland and 991 acres of primary managed wetland) to secondary tidal
  brackish emergent wetland. The hypothetical restoration footprints in Suisun Marsh overlap
  with 13 CNDDB records for salt marsh harvest mouse (California Department of Fish and
  Wildlife 2013); however, the BDCP’s conservation actions assume that all suitable habitat in
  Suisun Marsh is occupied by the species.

- **CM11 Natural Communities Enhancement and Management:** As described in the BDCP, the
  restoration of at least 1,500 acres of tidal brackish emergent wetland would be managed to
  provide viable habitat for salt marsh harvest mouse and the protection of 1,500 acres of
  managed wetland specifically to be managed for salt marsh harvest mouse. A variety of habitat
  management actions included in **CM11 Natural Communities Enhancement and Management** that
  are designed to enhance and manage these areas for salt marsh harvest mouse and may result in
  localized ground disturbances that could temporarily remove small amounts of salt marsh
  harvest mouse habitat. The restoration of tidal brackish emergent wetlands, the protection
  managed wetlands, and the protection and/or restoration of grasslands within 200 feet of
  restored salt marsh harvest mouse habitat would also have enhancement and management
  actions that would include invasive species control, nonnative wildlife control, and vegetation
  management. Ground-disturbing activities, such as removal of nonnative vegetation are
  expected to have minor effects on habitat and are expected to result in overall improvements to
  and maintenance of salt marsh harvest mouse habitat values over the term of the BDCP. These
  effects cannot be quantified, but are expected to be minimal and would be avoided and
  minimized by the AMMs listed below.

- **Injury and Direct Mortality:** The use of heavy equipment and handtools may result in injury or
  mortality to salt marsh harvest mouse during restoration, enhancement, and management
  activities. However, preconstruction surveys, construction monitoring, and other measures
  would be implemented to avoid and minimize injury or mortality of this species during these
  activities, as required by the AMMs listed below.

The following paragraphs summarize the combined effects discussed above and describe other
BDCP conservation actions that offset or avoid these effects. NEPA and CEQA impact conclusions are
also included.

**Near-Term Timeframe**

The near-term BDCP conservation strategy has been evaluated to determine whether it would
provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that
the effects of near-term covered activities would not be adverse under NEPA and would be less than
significant under CEQA. Alternative 1B would affect 2,465 acres of salt marsh harvest mouse
modeled habitat in the study area in the near-term. These effects include 1,517 acres of permanent
loss and 948 acres of converted habitat. Most of the habitat converted would be from primary
heterotrophic (599 acres consisting of 64 acres of tidal brackish emergent wetland and 534 acres of
managed wetland) to secondary tidal brackish emergent wetland.

The BDCP has committed to near-term goals of restoring 2,000 acres of tidal brackish emergent
wetland, the protection and/or restoration of grasslands within 200 feet of restored tidal wetlands,
and the protection and enhancement of 1,500 acres of managed wetlands for salt marsh harvest
mouse. Though there would be a net loss of modeled habitat, nearly all of these losses (97%) are to
managed wetlands, which according to the U.S. Fish and Wildlife Service are at high risk of
catastrophic flooding (U.S. Fish and Wildlife Service 2010) and have lower long-term conservation
value than tidal wetlands. The species-specific biological goals and objectives would inform the
near-term protection and restoration efforts. These Plan goals represent performance standards for
considering the effectiveness of restoration actions. The acres of protection and restoration
contained in the near-term Plan goals would keep pace with the loss of habitat and effects on salt
marsh harvest mouse.

Other factors relevant to effects on salt marsh harvest mouse are listed below.

- Tidal restoration actions would not immediately displace salt marsh harvest mouse in managed
  wetlands as noted in the specie’s draft recovery plan, because the conversion of managed
  wetland to tidal marsh would be gradual. Tidal marsh restoration is often accomplished by
  breaching levees and converting diked nontidal marsh currently occupied by salt marsh harvest
  mouse populations to tidal wetlands, their historic condition. Conversion of these subsided
  areas requires sedimentation and accretion over time to restore marsh plains, resulting in a
  prolonged period (sometimes a decade or more) in which resident mice populations are
  displaced by uninhabitable aquatic areas (U.S. Fish and Wildlife Service 2010). Despite these
temporary adverse effects, the draft recovery plan and Suisun Marsh Plan advocate strongly for
restoration of tidal wetlands through the conversion of managed wetlands. These plans are
based on the premise that managed wetlands are at high risk of loss of salt marsh harvest mouse
habitat from a variety of factors, including flooding from levee failure and cessation of active
management (which is often necessary to maintain habitat values in managed wetlands).
Therefore, the temporary effects under Alternative 1B would be consistent with those deemed
acceptable in the draft recovery plan for salt marsh harvest mouse and the Suisun Marsh Plan.

- Restoration in Suisun Marsh would be carefully phased over time to offset adverse effects of
  restoration as it occurs. This phasing would ensure that temporal loss as a result of tidal natural
  communities restoration does not adversely affect the salt marsh harvest mouse population,
  restoration in Suisun Marsh would be carefully phased over time to offset adverse effects of
  restoration as it occurs, ensure that short-term population loss is relatively small and
  incremental, and maintain local source populations to recolonize newly restored areas. The tidal
  restoration projects in Suisun Marsh would be implemented in 150-acre or greater patches that
  provide viable habitat areas for the salt marsh harvest mouse habitat consistent with the draft
  tidal marsh recovery plan (U.S. Fish and Wildlife Service 2010).

- The salt marsh harvest mouse population would be monitored during the phasing process (see
  BDCP Chapter 3, Section 3.4.4.3.4.), and adaptive management would be applied to ensure
  maintenance of the population as described in the BDCP (BDCP Chapter 3, Section 3.4.4.4 and
  Section 3.6).

- The BDCP commits to manage reserve areas so that perennial pepperweed cover is no more
  than 10% in tidal brackish emergent wetlands (Objective TBEWNC2.1), which would benefit
pickleweed production in the marsh. Salt marsh harvest mouse depends on pickleweed for forage and cover.

Because there would be no project-level impacts on salt marsh harvest mouse from CM1, the analysis of the effects of conservation actions does not include a comparison with standard ratios used for project-level NEPA analyses.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, and AMM26 Salt Marsh Harvest Mouse and Suisun Shrew. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C.

**Late Long-Term Timeframe**

Based on modeled habitat, the study area supports approximately 35,588 acres of salt marsh harvest mouse modeled habitat. Alternative 1B as a whole would result in effects on 6,968 acres of saltmarsh harvest mouse modeled habitat over the term of the Plan, which would include 5,376 acres of permanent losses and 1,592 acres of habitat conversions. These effects (loss and conversion) would be to 20% of the modeled habitat in the study area. Most of these effects (99%) would be to managed wetlands, which though are known to be occupied by salt marsh harvest mouse are at high risk of catastrophic flooding and have a lower long-term conservation value than tidal wetlands (U.S. Fish and Wildlife Service 2010). Effects on up to 20% of the species’ habitat in the Plan Area may diminish the salt marsh harvest mouse population in the Plan Area and result in reduced genetic diversity, thereby putting the local population at risk of local extirpation due to random environmental fluctuations or catastrophic events. This effect is expected to be greatest if large amounts of habitat are removed at one time in Suisun Marsh and are not effectively restored for many years, and if there are no adjacent lands with salt marsh harvest mouse populations to recolonize restored areas.

The Plan includes a commitment to restore or create 6,000 acres of tidal brackish emergent wetland, 1,500 acres of which would target middle and high marsh habitat (primary habitat for salt marsh harvest mouse) (Objectives TBEWNC1.1, TBEWNC1.2, and SMHM1.1, associated with CM4); the protection of 6,500 acres of managed wetlands, 1,500 acres of which would be specifically managed for salt marsh harvest mouse (Objectives SMHM1.2 and MWNC1.1, associated with CM3), and the protection and/or restoration of grassland adjacent to tidal restoration (areas within 200 feet of tidal restoration) to provide upland refugia for salt marsh harvest mouse (Objective GNC1.4, associated with). Other factors relevant to effects on salt marsh harvest mouse are listed here.

- Tidal restoration actions would not immediately displace salt marsh harvest mouse in managed wetlands as noted in the draft recovery plan for salt marsh harvest mouse because the conversion of managed wetland to tidal marsh would be gradual. Tidal marsh restoration is often accomplished by breaching levees and converting diked nontidal marsh currently occupied by salt marsh harvest mouse populations to tidal wetlands, their historic condition. Conversion of these subsided areas requires sedimentation and accretion over time to restore marsh plains, resulting in a prolonged period (sometimes a decade or more) in which resident mice populations are displaced by uninhabitable aquatic areas (U.S. Fish and Wildlife Service 2010). Despite these temporary adverse effects, the draft recovery plan and Suisun Marsh Plan advocate strongly for restoration of tidal wetlands through the conversion of managed wetlands.
These plans are based on the premise that managed wetlands are at high risk of loss of salt marsh harvest mouse habitat from a variety of factors, including flooding from levee failure and cessation of active management (which is often necessary to maintain habitat values in managed wetlands). Therefore, the temporary effects under BDCP are consistent with those deemed acceptable in the draft recovery plan for salt marsh harvest mouse and the Suisun Marsh Plan. Despite these temporary adverse effects, the draft recovery plan and Suisun Marsh Plan advocate strongly for restoration of tidal wetlands through the conversion of managed wetlands. These plans are based on the premise that managed wetlands are at high risk of loss of salt marsh harvest mouse habitat from a variety of factors, including flooding from levee failure and cessation of active management (which is often necessary to maintain habitat values in managed wetlands). Therefore, the temporary effects under BDCP are consistent with those deemed acceptable in the draft recovery plan for salt marsh harvest mouse and the Suisun Marsh Plan.

- In order to ensure that temporal loss as a result of tidal natural communities restoration does not adversely affect the salt marsh harvest mouse population, restoration in Suisun Marsh would be carefully phased over time to offset adverse effects of restoration as it occurs, ensure that short-term population loss is relatively small and incremental, and maintain local source populations to recolonize newly restored areas. The tidal restoration projects in Suisun Marsh would be implemented in 150-acre or greater patches that provide viable habitat areas for the salt marsh harvest mouse habitat consistent with the draft tidal marsh recovery plan (U.S. Fish and Wildlife Service 2010).

- The salt marsh harvest mouse population would be monitored during the phasing process (see BDCP Chapter 3, Section 3.4.4.3.4), and adaptive management would be applied to ensure maintenance of the population as described in the BDCP (BDCP Chapter 3, Section 3.4.4.4 and Section 3.6).

- The BDCP commits to manage reserve areas so that perennial pepperweed cover is no more than 10% in tidal brackish emergent wetlands (Objective TBEWNC2.1), which would benefit pickleweed production in the marsh. Salt marsh harvest mouse depends on pickleweed for forage and cover.

- The habitat that would be restored and protected would consist of large blocks of contiguous tidal brackish emergent wetland that has a large proportion of pickleweed-dominated vegetation suitable for the species. This would provide greater habitat connectivity and greater habitat value, which is expected to accommodate larger populations and to therefore increase population resilience to random environmental events and climate change.

The BDCP’s beneficial effects analysis (BDCP Chapter 5, Section 5.6, Effects on Covered Wildlife and Plant Species) estimates that the restoration and protection actions discussed above could result in the restoration of 6,046 acres and the protection of 1,550 acres of modeled habitat for salt marsh harvest mouse.

**NEPA Effects:** In the absence of other conservation actions, the effects on salt marsh harvest mouse habitat from Alternative 1B in the near-term would represent an adverse effect as a result of habitat modification and potential direct mortality of a special-status species. However, the BDCP has committed to habitat protection, restoration, management, and enhancement associated with CM3, CM4, CM8, and CM11. This habitat protection, restoration, management, and enhancement would be guided by species-specific goals and objectives and by AMM1–AMM5 and AMM26, which would be in place throughout the construction period. Considering these commitments, losses and
conversions of salt marsh harvest mouse habitat and potential mortality of individuals under Alternative 1B would not be an adverse effect.

**CEQA Conclusion:**

**Near-Term Timeframe**

The near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the impacts of near-term covered activities would be less than significant under CEQA. Alternative 1B would affect 2,465 acres of salt marsh harvest mouse modeled habitat in the study area in the near-term. These effects include 1,517 acres of permanent loss and 948 acres of converted habitat. Most of the habitat converted would be to primary habitats (599 acres consisting of 64 acres of tidal brackish emergent wetland and 534 acres of managed wetland) to secondary tidal brackish emergent wetland.

The BDCP has committed to near-term goals of restoring 2,000 acres of tidal brackish emergent wetland, the protection and/or restoration of grasslands within 200 feet of restored tidal wetlands, and the protection and enhancement of 1,500 acres of managed wetlands for salt marsh harvest mouse. Though there would be a net loss of modeled habitat, nearly all of these losses (97%) are to managed wetlands, which according to the U.S. Fish and Wildlife Service are at high risk of catastrophic flooding (U.S. Fish and Wildlife Service 2010) and have lower long-term conservation value than tidal wetlands. The species-specific biological goals and objectives would inform the near-term protection and restoration efforts. These Plan goals represent performance standards for considering the effectiveness of restoration actions. The acres of protection and restoration contained in the near-term Plan goals would keep pace with the loss of habitat and effects on salt marsh harvest mouse habitat.

Other factors relevant to effects on salt marsh harvest mouse are listed below.

- Tidal restoration actions would not immediately displace salt marsh harvest mouse in managed wetlands as noted in the specie’s draft recovery plan because the conversion of managed wetland to tidal marsh would be gradual. Tidal marsh restoration is often accomplished by breaching levees and converting diked nontidal marsh currently occupied by salt marsh harvest mouse populations to tidal wetlands, their historic condition. Conversion of these subsided areas requires sedimentation and accretion over time to restore marsh plains, resulting in a prolonged period (sometimes a decade or more) in which resident mice populations are displaced by uninhabitable aquatic areas (U.S. Fish and Wildlife Service 2010). Despite these temporary adverse effects, the draft recovery plan and Suisun Marsh Plan advocate strongly for restoration of tidal wetlands through the conversion of managed wetlands. These plans are based on the premise that managed wetlands are at high risk of loss of salt marsh harvest mouse habitat from a variety of factors, including flooding from levee failure and cessation of active management (which is often necessary to maintain habitat values in managed wetlands). Therefore, the temporary effects under Alternative 1B would be consistent with those deemed acceptable in the draft recovery plan for salt marsh harvest mouse and the Suisun Marsh Plan.

- To ensure that temporal loss as a result of tidal natural communities restoration does not adversely affect the salt marsh harvest mouse population, restoration in Suisun Marsh would be carefully phased over time to offset adverse effects of restoration as it occurs, ensure that short-term population loss is relatively small and incremental, and maintain local source populations
to recolonize newly restored areas. The tidal restoration projects in Suisun Marsh would be implemented in 150-acre or greater patches that provide viable habitat areas for the salt marsh harvest mouse habitat consistent with the draft tidal marsh recovery plan (U.S. Fish and Wildlife Service 2010).

- The salt marsh harvest mouse population would be monitored during the phasing process (see BDCP Chapter 3, Section 3.4.4.3.4.), and adaptive management would be applied to ensure maintenance of the population as described in the BDCP (BDCP Chapter 3, Section 3.4.4.4 and Section 3.6).

- The BDCP commits to manage reserve areas so that perennial pepperweed cover is no more than 10% in tidal brackish emergent wetlands (Objective TBEWNC2.1), which would benefit pickleweed production in the marsh. Salt marsh harvest mouse depends on pickleweed for forage and cover.

Because there would be no project-level impacts on salt marsh harvest mouse from CM1, the analysis of the effects of conservation actions does not include a comparison with standard ratios used for project-level CEQA analyses.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, and AMM26 Salt Marsh Harvest Mouse and Suisun Shrew. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C.

These commitments are more than sufficient to support the conclusion that the near-term impacts of Alternative 1B would be less than significant.

**Late Long-Term Timeframe**

The study area supports approximately 35,588 acres of salt marsh harvest mouse modeled habitat. Alternative 1B as a whole would result in effects on 6,968 acres of saltmarsh harvest mouse modeled habitat over the term of the Plan, which would include 5,376 acres of permanent losses and 1,592 acres of habitat conversions. The Plan includes a commitment to restore or create 6,000 acres of tidal brackish emergent wetland, 1,500 acres of which would target middle and high marsh habitat (primary habitat for salt marsh harvest mouse) (Objectives TBEWNC1.1, TBEWNC1.2, and SMHM1.1, associated with CM4); the protection of 6,500 acres of managed wetlands, 1,500 acres of which would be specifically managed for salt marsh harvest mouse (Objectives SMHM1.2 and MWNC1.1, associated with CM3), and the protection and/or restoration of grassland adjacent to tidal restoration (areas within 200 feet of tidal restoration) to provide upland refugia for salt marsh harvest mouse (Objective GNC1.4, associated with CM3 and CM8). Other factors relevant to effects on salt marsh harvest mouse include:

- Tidal restoration actions would not immediately displace salt marsh harvest mouse in managed wetlands as noted in the draft recovery plan for salt marsh harvest mouse because the conversion of managed wetland to tidal marsh would be gradual. Tidal marsh restoration is often accomplished by breaching levees and converting diked nontidal marsh currently occupied by salt marsh harvest mouse populations to tidal wetlands, their historic condition. Conversion of these subsided areas requires sedimentation and accretion over time to restore marsh plains, resulting in a prolonged period (sometimes a decade or more) in which resident
mice populations are displaced by uninhabitable aquatic areas (U.S. Fish and Wildlife Service 2010). Despite these temporary adverse effects, the draft recovery plan and Suisun Marsh Plan advocate strongly for restoration of tidal wetlands through the conversion of managed wetlands. These plans are based on the premise that managed wetlands are at high risk of loss of salt marsh harvest mouse habitat from a variety of factors, including flooding from levee failure and cessation of active management (which is often necessary to maintain habitat values in managed wetlands). Therefore, the temporary effects under BDCP are consistent with those deemed acceptable in the draft recovery plan for salt marsh harvest mouse and the Suisun Marsh Plan.

- In order to ensure that temporal loss as a result of tidal natural communities restoration does not adversely affect the salt marsh harvest mouse population, restoration in Suisun Marsh would be carefully phased over time to offset adverse effects of restoration as it occurs, ensure that short-term population loss is relatively small and incremental, and maintain local source populations to recolonize newly restored areas. The tidal restoration projects in Suisun Marsh would be implemented in 150-acre or greater patches that provide viable habitat areas for the salt marsh harvest mouse habitat consistent with the draft tidal marsh recovery plan (U.S. Fish and Wildlife Service 2010).

- The salt marsh harvest mouse population would be monitored during the phasing process (see BDCP Chapter 3, Section 3.4.4.3.4.), and adaptive management would be applied to ensure maintenance of the population as described in the BDCP (BDCP Chapter 3, Section 3.4.4.4 and Section 3.6).

- The BDCP commits to manage reserve areas so that perennial pepperweed cover is no more than 10% in tidal brackish emergent wetlands (Objective TBEWNC2.1), which would benefit pickleweed production in the marsh. Salt marsh harvest mouse depends on pickleweed for forage and cover.

- The habitat that would be restored and protected would consist of large blocks of contiguous tidal brackish emergent wetland that has a large proportion of pickleweed-dominated vegetation suitable for the species. This would provide greater habitat connectivity and greater habitat value, which is expected to accommodate larger populations and to therefore increase population resilience to random environmental events and climate change.

The BDCP’s beneficial effects analysis (BDCP Chapter 5, Section 5.6, Effects on Covered Wildlife and Plant Species) estimates that the restoration and protection actions discussed above could result in the restoration of 6,046 acres and the protection of 1,550 acres of modeled habitat for salt marsh harvest mouse.

Alternative 1B would result in substantial modifications to salt marsh harvest mouse habitat in the absence of other conservation actions. However, with habitat protection, restoration, management, and enhancement associated with CM3, CM4, CM8, and CM11, guided by species-specific goals and objectives and by AMM1–AMM5 and AMM26, which would be in place throughout the time period of construction, Alternative 1B over the term of the BDCP would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the number or restrict the range of the species. Therefore, the alternative would have a less-than-significant impact on salt marsh harvest mouse.
Impact BIO-159: Indirect Effects of Plan Implementation on Salt Marsh Harvest Mouse

Construction/disturbance activities associated tidal restoration (CM4), grassland restoration (CM8), and management and enhancement activities (CM11) could result in temporary noise and visual disturbances to salt marsh harvest mouse occurring within 100 feet of these areas over the term of the BDCP. These potential effects would be minimized or avoided through AMM1–AMM5, and AMM26, which would be in effect throughout the term of the Plan.

The use of mechanical equipment during the implementation of the conservation measures could cause the accidental release of petroleum or other contaminants that could affect salt marsh harvest mouse and its habitat. The inadvertent discharge of sediment could also have a negative effect on the species and its habitat. AMM1–AMM5 would minimize the likelihood of such spills and would ensure measures are in place to prevent runoff from the construction area and potential effects of sediment on salt marsh harvest mouse.

Tidal marsh restoration has the potential to increase salt marsh harvests mouse’s exposure to mercury. Mercury is transformed into the more bioavailable form of methylmercury under anaerobic conditions, which in the environment typically occurs in sediments subjected to regular wetting and drying such as tidal marshes and flood plains. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury. In general, the highest methylation rates are associated with high tidal marshes that experience intermittent wetting and drying and associated anoxic conditions (Alpers et al. 2008). High tidal marsh is considered to be primary habitat for salt marsh harvest mouse and thus the species could be exposed to methyl mercury in tidal restoration areas. Salt marsh harvest mouse may be exposed to elemental mercury by feeding on pickleweed, which is found concentrated in the distal tips of pickleweed leaves (Yee et al., 2008). Though elemental mercury is less bioavailable than methylmercury, studies have shown that mercury can become methylated in the anaerobic portions of the intestinal tract (Rudd et al. 1980, Rieder et al. 2013) and could thus become a pathway for salt marsh harvest exposure to methylmercury. A study of small mammals residing in pickleweed around the San Francisco Bay showed an absence of salt marsh harvest mouse where mercury concentrations measured in house mice (Mus musculus) livers were ≥0.19 μg/g (dry weight) (Clark et al. 1992). Clark et al (1992) also report that the lack of salt marsh harvest mouse at these locations are not the result of undetected habitat differences or are by chance. Clarke et al (1992) suggest that the absence of salt marsh harvest mouse at certain locations may be associated with higher amounts of mercury and polychlorinated biphenyls (PCBs); however, because their study didn’t analyze contaminants in salt marsh harvest mouse and because (at that time) there was no data in the literature on contaminants in harvest mice, they could not make conclusions on these associations. Currently, it is unknown what the exact exposure pathways are or what tissue concentrations are harmful to the salt marsh harvest mouse.

The Suisun Marsh Plan (Bureau of Reclamation et al. 2010) anticipates that tidal wetlands restored under the plan would generate less methylmercury than the existing managed wetlands. The potential for salt marsh harvest mouse exposure to methyl mercury in Suisun Marsh may decrease in the long term because the creation of tidal brackish emergent wetland would predominantly result from the conversion of managed wetlands. CM12 Methylmercury Management includes provisions for project-specific Mercury Management Plans. Along with avoidance and minimization measures and adaptive management and monitoring, CM12 could reduce the effects of methylmercury on salt marsh harvest mouse resulting from BDCP tidal restoration.
NEPA Effects: Implementation of the AMMs listed above as part of implementing BDCP Alternative 1B would avoid and minimize indirect effects on salt marsh harvest mouse. These AMMs would also avoid and minimize effects that could substantially reduce the number of salt marsh harvest mouse, or restrict the species’ range. Therefore, the indirect effects of Alternative 1B would not have an adverse effect on salt marsh harvest mouse.

CEQA Conclusion: Indirect effects from construction-related noise and visual disturbances could impact salt marsh harvest mouse within 100 feet of these disturbances. The use of mechanical equipment during construction could cause the accidental release of petroleum or other contaminants that could impact salt marsh harvest mouse and its habitat. The inadvertent discharge of sediment adjacent to salt marsh harvest mouse habitat could also impact the species. With implementation of AMM1–AMM5 and AMM26 as part of Alternative 1B construction, operation and maintenance, the BDCP would avoid the potential for substantial adverse effects on salt marsh harvest mouse, either indirectly or through habitat modifications, in that the BDCP would not result in a substantial reduction in numbers or a restriction in the range of salt marsh harvest mouse. The indirect effects of BDCP Alternative 1B would have a less-than-significant impact on salt marsh harvest mouse.

Salt marsh harvest mouse could experience indirect effects from increased exposure to methylmercury as a result of tidal habitat restoration (CM4). With implementation of CM12, the potential indirect effects of methylmercury would not result in a substantial reduction in numbers or a restriction in the range of salt marsh harvest mouse, and, therefore, would have a less-than-significant impact on the species.

Suisun Shrew

Primary Suisun shrew habitat consists of all Salicornia-dominated natural seasonal wetlands and certain Scirpus and Typha communities found within Suisun Marsh only. Low marsh dominated by Schoenoplectus acutus and S. californicus and upland transitional zones within 150 feet of the tidal wetland edge were classified separately as secondary habitat because they are used seasonally (Hays and Lidicker 2000). All managed wetlands were excluded from the habitat model. Construction and restoration associated with Alternative 1B would also include the following conservation actions over the term of the BDCP to benefit Suisun shrew (BDCP Chapter 3, Conservation Strategy).

- Restore or create 6,000 acres of tidal brackish emergent wetland in CZ 11 to be consistent with the final Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California (Objective TBEWNC1.1, associated with CM4)
- Within the 6,000 acres of tidal brackish emergent wetland restored or created, distribute 1,500 acres of middle and high marsh (primary Suisun shrew habitat) to contribute to total (existing and restored) acreage targets for each complex as specified in the final Recovery Plan for Tidal Marsh Ecosystems of Northern and Central California (Objective TBEWNC1.2, associated with CM4).
- Limit perennial pepperweed to no more than 10% cover in the tidal brackish emergent wetland natural community within the reserve system (Objective TBEWNC2.1).
- Protect or restore grasslands adjacent to restored tidal brackish emergent wetlands to provide at least 200 feet of adjacent grasslands beyond the sea level rise accommodation area, which provides refugia during high tides (Objective GNC1.4, associated with CM3 and CM8).
As explained below, with the restoration or protection of these amounts of habitat, impacts on the Suisun shrew would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

a See Appendix 12E for detailed breakdown of conservation measure effects over the BDCP’s near-term and late long-term timeframes.

b See discussion below for a description of applicable CMs.

c LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

d Periodic effects were estimated for the late long-term only.

NT = near-term
LLT = late long-term
NA = not applicable

Impact BIO-160: Loss or Conversion of Habitat for and Direct Mortality of Suisun shrew

BDCP tidal restoration (CM4) would be the only conservation measure resulting in loss of habitat to Suisun shrew. Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. Each of these activities is described in detail below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- **CM4 Tidal Natural Communities Restoration** would result in effects on 401 acres of Suisun shrew modeled habitat, which would include 377 acres of permanent losses and 24 acres of habitat conversions. Suisun shrew may be displaced temporarily from areas of converted habitat but would ultimately provide suitable habitat for the species. However, all 9 acres would be converted from secondary to primary habitat and therefore over would be net benefit to the species. The hypothetical restoration footprints overlap with two CNDDDB records for Suisun shrew (California Department of Fish and Wildlife 2013).

- **CM11 Natural Communities Enhancement and Management**: As described in the BDCP, the restoration of at least 6,000 acres of tidal brackish emergent wetland would be managed to provide habitat for covered species, including Suisun shrew. A variety of habitat management actions included in **CM11 Natural Communities Enhancement and Management** that are designed to enhance and manage these areas may result in localized ground disturbances that could
temporarily remove small amounts of Suisun shrew habitat. The areas of grasslands that would be protected and/or restored within 200 feet of restored tidal marsh would also have enhancement and management actions that would include invasive species control, nonnative wildlife control, and vegetation management. Ground-disturbing activities, such as removal of nonnative vegetation are expected to have minor effects on habitat and are expected to result in overall improvements to and maintenance of Suisun shrew habitat values over the term of the BDCP. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized by the AMMs listed below.

- Injury and Direct Mortality: The use of heavy equipment and handtools may result in injury or mortality to Suisun shrew during restoration, enhancement, and management activities. However, preconstruction surveys, construction monitoring, and other measures would be implemented to avoid and minimize injury or mortality of this species during these activities, as required by the AMM described below.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

**Near-Term Timeframe**

The near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the effects of near-term covered activities would not be adverse under NEPA. Alternative 1B would affect 105 acres of Suisun shrew modeled habitat in the study area in the near-term. These effects include 90 acres of permanent loss and 15 acres of converted habitat, which is all secondary habitat being converted to primary habitat.

The BDCP has committed to near-term goals of restoring 2,000 acres of tidal brackish emergent wetland and the protection and/or restoration of grasslands within 200 feet of restored tidal wetlands, of which approximately 150 feet of this area would benefit the species. These Plan goals represent performance standards for considering the effectiveness of restoration actions. The acres of tidal restoration and the commitment to protection of adjacent uplands contained in the near-term Plan goals would keep pace with the loss of habitat and effects on Suisun shrew.

Other factors relevant to effects on Suisun shrew.

- Restoration would be sequenced and oriented in a manner that minimizes any temporary, initial loss of habitat and habitat fragmentation
- The habitat that would be restored and protected would consist of large blocks of contiguous tidal brackish emergent wetland that has a large proportion of pickleweed-dominated vegetation suitable for the species. This would provide greater habitat connectivity and greater habitat value and quantity, with is expected to accommodate larger populations and to therefore increase population resilience to random environmental events and climate change.
- The amount of tidal habitat restored in the near-term (2,000 acres) would greatly exceed the amount permanently lost (105 acres).

Because there would be no project-level impacts on Suisun shrew resulting from CM1, the analysis of the effects of conservation actions does not include a comparison with standard ratios used for project-level NEPA analyses.
The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, and AMM26 Salt Marsh Harvest Mouse and Suisun Shrew. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C.

Late Long-Term Timeframe

Based on modeled habitat, the study area supports approximately 7,515 acres of Suisun shrew modeled habitat. Alternative 1B as a whole would result in effects on 401 acres of Suisun shrew modeled habitat over the term of the Plan, which would include 377 acres of permanent losses and 24 acres of habitat conversions (roughly 5% of the habitat in the study area). The Plan includes a commitment to restore or create 6,000 acres of tidal brackish emergent wetland, 1,500 acres of which would target middle and high marsh habitat (primary habitat for Suisun shrew) (Objectives TBEWNC1.1, TBEWNC1.2, SMHM1.1, associated with CM4) and the protection and/or restoration of grassland adjacent to tidal restoration (areas within 200 feet of tidal restoration, of which approximately 150 feet of this area would benefit the species) to provide upland refugia for Suisun shrew (Objective GNC1.4, associated with CM3 and CM8). Other factors relevant to effects on Suisun shrew are listed here.

- Restoration would be sequenced and oriented in a manner that minimizes any temporary, initial loss of habitat and habitat fragmentation.
- The habitat that would be restored and protected would consist of large blocks of contiguous tidal brackish emergent wetland that has a large proportion of pickleweed-dominated vegetation suitable for the species. This would provide greater habitat connectivity and greater habitat value and quantity, with is expected to accommodate larger populations and to therefore increase population resilience to random environmental events and climate change.
- The amount of tidal habitat restored (6,000 acres) greatly exceeds the amount permanently lost and converted (401 acres).

The BDCP’s beneficial effects analysis (BDCP Chapter 5, Section 5.6, Effects on Covered Wildlife and Plant Species) estimates that the restoration and protection actions discussed above could result in the restoration of 6,006 acres and the protection of 232 acres of modeled habitat for Suisun shrew.

NEPA Effects: In the absence of other conservation actions, the effects on Suisun shrew habitat from Alternative 1B would represent an adverse effect as a result of habitat modification and potential direct mortality of a special-status species. However, the BDCP has committed to habitat protection, restoration, management, and enhancement associated with CM3, CM4, CM8, and CM11. This habitat protection, restoration, management, and enhancement would be guided by biological goals and objectives and by AMM1–AMM5 and AMM26, which would be in place throughout the construction period. Considering these commitments, losses and conversions of Suisun shrew habitat and potential mortality of individuals in both the near-term and the late long-term under Alternative 1B would not be an adverse effect.
CEQA Conclusion:

Near-Term Timeframe

The near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the impacts of near-term covered activities would be less than significant under CEQA. Alternative 1B would impact 105 acres of Suisun shrew modeled habitat in the study area in the near-term. These effects include 90 acres of permanent loss and 15 acres of converted habitat, which is all secondary habitat being converted to primary habitat.

The BDCP has committed to near-term goals of restoring 2,000 acres of tidal brackish emergent wetland and the protection and/or restoration of grasslands within 200 feet of restored tidal wetlands, of which approximately 150 feet of this area would benefit the species. These Plan goals represent performance standards for considering the effectiveness of restoration actions. The acres of tidal restoration and the commitment to protection of adjacent uplands contained in the near-term Plan goals would keep pace with the loss of habitat and effects on Suisun shrew.

Other factors relevant to effects on Suisun shrew.

- Restoration would be sequenced and oriented in a manner that minimizes any temporary, initial loss of habitat and habitat fragmentation
- The habitat that would be restored and protected would consist of large blocks of contiguous tidal brackish emergent wetland that has a large proportion of pickleweed-dominated vegetation suitable for the species. This would provide greater habitat connectivity and greater habitat value and quantity, with is expected to accommodate larger populations and to therefore increase population resilience to random environmental events and climate change.
- The amount of tidal habitat restored in the near term (2,000 acres) greatly exceeds the amount permanently lost (105 acres).

Because there would be no project-level impacts on Suisun shrew resulting from CM1, the analysis of the effects of conservation actions does not include a comparison with standard ratios used for project-level CEQA analyses.

The Plan also includes commitments to AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, and AMM26 Salt Marsh Harvest Mouse and Suisun Shrew. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas. The AMMs are described in detail in BDCP Appendix 3.C.

These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 1B would be less than significant under CEQA.

Late Long-Term Timeframe

The study area supports approximately 7,515 acres of Suisun shrew modeled habitat. Alternative 1B as a whole would result in effects on 401 acres of Suisun shrew modeled habitat over the term of the Plan, which would include 377 acres of permanent losses and 24 acres of habitat conversions (roughly 5% of the habitat in the study area). The Plan includes a commitment to restore or create 6,000 acres of tidal brackish emergent wetland, 1,500 acres of which would target middle and high
marsh habitat (primary habitat for Suisun shrew) (Objectives TBEWNC1.1, TBEWNC1.2, and
SMHM1.1, associated with CM4) and the protection and/or restoration of grassland adjacent to tidal
restoration (areas within 200 feet of tidal restoration, of which approximately 150 feet of this area
would benefit the species) to provide upland refugia for Suisun shrew (Objective GNC1.4, associated
with CM3 and CM8). Other factors relevant to effects on Suisun shrew are listed here.

- Restoration would be sequenced and oriented in a manner that minimizes any temporary, initial
  loss of habitat and habitat fragmentation
- The habitat that would be restored and protected would consist of large blocks of contiguous
tidal brackish emergent wetland that has a large proportion of pickleweed-dominated
vegetation suitable for the species. This would provide greater habitat connectivity and greater
habitat value and quantity, with is expected to accommodate larger populations and to therefore
increase population resilience to random environmental events and climate change.
- The amount of tidal habitat restored (6,000 acres) greatly exceeds the amount permanently lost
  (401 acres).

The BDCP’s beneficial effects analysis (BDCP Chapter 5, Section 5.6, Effects on Covered Wildlife and
Plant Species) estimates that the restoration and protection actions discussed above could result in
the restoration of 6,006 acres and the protection of 232 acres of modeled habitat for Suisun shrew.

Alternative 1B would result in substantial modifications to Suisun shrew habitat in the absence of
other conservation actions. However, with habitat protection, restoration, management, and
enhancement associated with CM3, CM4, CM8 and CM11, guided by species-specific goals and
objectives and by AMM1–AMM5 and AMM26, which would be in place throughout the construction
phase, Alternative 1B over the term of the BDCP would not result in a substantial adverse effect
through habitat modifications and would not substantially reduce the number or restrict the range
of the species. Therefore, the alternative would have a less-than-significant impact on Suisun shrew.

Impact BIO-161: Indirect Effects of Plan Implementation on Suisun Shrew

Construction/disturbance activities associated tidal restoration (CM4), grassland restoration (CM8),
and management and enhancement activities (CM11) could result in temporary noise and visual
disturbances to Suisun shrew occurring within 100 feet of these areas over the term of the BDCP.
These potential effects would be minimized or avoided through AMM1–AMM5, and AMM26, which
would be in effect throughout the term of the Plan.

The use of mechanical equipment during the implementation of the conservation measures could
cause the accidental release of petroleum or other contaminants that could affect Suisun shrew and
its habitat. The inadvertent discharge of sediment could also have a negative effect on the species
and its habitat. AMM1–AMM5 would minimize the likelihood of such spills and would ensure
measures are in place to prevent runoff from the construction area and potential effects of sediment
on Suisun shrew.

Tidal marsh restoration has the potential to increase Suisun shrew’s exposure to mercury. Mercury
is transformed into the more bioavailable form of methylmercury under anaerobic conditions,
which in the environment typically occurs in sediments subjected to regular wetting and drying
such as tidal marshes and flood plains. Thus, BDCP restoration activities that create newly
inundated areas could increase bioavailability of mercury. In general, the highest methylation rates
are associated with high tidal marshes that experience intermittent wetting and drying and
associated anoxic conditions (Alpers et al. 2008). High and mid tidal marsh is considered to be primary habitat for Suisun shrew and thus the species could be exposed to methylmercury in tidal restoration areas. Suisun shrew could be exposed to methylmercury by feeding on marsh invertebrates that may bioaccumulate methylmercury from marsh sediments. Toxic concentrations of methylmercury have been found in the kidneys of shrews that inhabit contaminated sites and forage on earthworms and other prey that live within contaminated sediments (Talmage and Walton 1993; Hinton and Veiga 2002).

The Suisun Marsh Plan (Bureau of Reclamation et al. 2010) anticipates that tidal wetlands restored under the plan would generate less methylmercury than the existing managed wetlands. The potential for Suisun shrew exposure to methyl mercury in Suisun Marsh may decrease in the long term because the creation of tidal brackish emergent wetland would predominantly result from the conversion of managed wetlands. CM12 Methylmercury Management includes provisions for project-specific Mercury Management Plans. Along with avoidance and minimization measures and adaptive management and monitoring, CM12 could reduce the effects of methylmercury on Suisun shrew resulting from BDCP tidal restoration.

NEPA Effects: Implementation of the AMMs listed above as part of implementing Alternative 1B would avoid and minimize the potential for substantial adverse effects on Suisun shrew, either indirectly or through habitat modifications. These AMMs would also avoid and minimize effects that could substantially reduce the number of Suisun shrew, or restrict the species’ range. Therefore, the indirect effects of Alternative 1B would not have an adverse effect on Suisun shrew.

CEQA Conclusion: Indirect effects from construction-related noise and visual disturbances could impact Suisun shrew within 100 feet of these disturbances. The use of mechanical equipment during construction could cause the accidental release of petroleum or other contaminants that could impact Suisun shrew and its habitat. The inadvertent discharge of sediment adjacent to Suisun shrew habitat could also impact the species. With implementation of AMM1–AMM5 and AMM26 as part of Alternative 1B construction, operation and maintenance, the BDCP would avoid the potential for substantial adverse effects on Suisun shrew, either indirectly or through habitat modifications, in that the BDCP would not result in a substantial reduction in numbers or a restriction in the range of Suisun shrew. The indirect effects of BDCP Alternative 1B would have a less-than-significant impact on Suisun shrew.

Suisun shrew could experience indirect effects from increased exposure to methylmercury as a result of tidal habitat restoration (CM4). With implementation of CM12, the potential indirect effects of methylmercury would not result in a substantial reduction in numbers or a restriction in the range of Suisun shrew, and, therefore, would have a less-than-significant impact on the species.

San Joaquin Kit Fox and American Badger

Within the study area, the modeled habitat for the San Joaquin kit fox and potential habitat for the American badger is restricted to 5,327 acres of grassland habitat west of Clifton Court Forebay along the study area's southwestern edge, in CZ 7–CZ 10. The study area represents the extreme northeastern corner of the species' range in California, which extends westward and southward from the study area border. The northern range of the San Joaquin kit fox (including the study area) was most likely marginal habitat historically and has been further degraded due to development pressures, habitat loss, and fragmentation (Clark et al. 2007). CNDDB (California Department of Fish and Wildlife 2013) reports twelve occurrences of San Joaquin kit foxes along the extreme western edge of the Plan Area within CZ 8, south of Brentwood (Figure 12-49). However, Clark et al. (2007)
provide evidence that a number of CNDDB occurrences in the northern portion of the species’ range may be coyote pups misidentified as San Joaquin kit foxes. Smith et al. (2006) suggest that the northern range may possibly be a population sink for the San Joaquin kit fox.

Construction and restoration associated with Alternative 1B conservation measures would result in both temporary and permanent losses of San Joaquin kit and American badger habitat (Table 12-1B-59). Grassland restoration, and protection and management of natural communities could affect modeled San Joaquin kit fox habitat and potential American badger habitat. Full implementation of Alternative 1B would also include biological objectives over the term of the BDCP to benefit the San Joaquin kit fox which would also benefit American badger which uses similar habitat (BDCP Chapter 3, Conservation Strategy). The conservation strategy for the San Joaquin kit fox involves protecting and enhancing habitat in the northern extent of the species’ range to increase the likelihood that kit fox may reside and breed in the Plan Area; and providing connectivity to habitat outside the Plan Area. The conservation measures that would be implemented to achieve the biological goals and objectives are summarized below.

- Protect and improve habitat linkages that allow terrestrial covered and other native species to move between protected habitats within and adjacent to the Plan Area (Objective L3.1, associated with CM3-CM8, and CM11).
- Protect 150 acres of alkali seasonal wetland in CZ 1, CZ 8, and/or CZ 11 among a mosaic of protected grasslands and vernal pool complex (Objective ASWNC1.1, associated with CM3).
- Restore or create alkali seasonal wetlands in CZ 1, CZ 8, and/or CZ 11 (up to 72 acres of alkali seasonal wetland complex restoration) (Objective ASWNC1.2, associated with CM3 and CM9).
- Protect 600 acres of existing vernal pool complex in CZ 1, CZ 8, and/or CZ 11, primarily in core vernal pool recovery areas identified in the Recovery Plan for Vernal Pool Ecosystems of California and Southern Oregon (U.S. Fish and Wildlife Service 2005) (Objective VPNC1.1, associated with CM3).
- Restore vernal pool complex in CZ 1, CZ 8, and/or CZ 11 to achieve no net loss of vernal pool acreage (up to 67 acres of vernal pool complex restoration) (Objective VPNC1.2, associated with CM3 and CM9).
- Protect 8,000 acres of grassland (Objective GNC1.1, associated with CM3).
- Restore 2,000 acres of grasslands to connect fragmented patches of protected grassland (Objective GNC1.2, associated with CM3 and CM8).
- Increase burrow availability for burrow-dependent species in grasslands surrounding alkali seasonal wetlands within restored and protected alkali seasonal wetland complex (Objective ASWNC2.3, associated with CM11).
- Increase prey, especially small mammals and insects, for grassland-foraging species in grasslands surrounding alkali seasonal wetlands within restored and protected alkali seasonal wetland complex (Objective ASWNC2.4, associated with CM11).
- Increase burrow availability for burrow-dependent species in grasslands surrounding vernal pools within restored and protected vernal pool complex (Objective VPNC2.4, associated with CM11).
- Increase prey, especially small mammals and insects, for grassland-foraging species in grasslands surrounding vernal pools within restored and protected vernal pool complex (Objective VPNC2.5, associated with CM11).

- Increase burrow availability for burrow-dependent species (Objective GNC2.3, associated with CM11).

- Increase prey abundance and accessibility, especially small mammals and insects, for grassland-foraging species (Objective GNC2.4, associated with CM11).

As explained below, with the restoration and protection of these amounts of habitat, in addition to the AMMs to reduce potential effects, impacts on San Joaquin kit fox and American badger would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

### Impact BIO-162: Loss or Conversion of Habitat for and Direct Mortality of San Joaquin Kit Fox and American Badger

Alternative 1B conservation measures would result in the permanent and temporary loss combined of 345 acres of modeled habitat for the San Joaquin kit fox (Table 12-1B-59). Because American badger uses grasslands for denning and foraging and shares the same geographic locations as the San Joaquin kit fox, effects on are anticipated to be the same as those described for San Joaquin kit fox. There is one San Joaquin kit fox and no American badger occurrences that overlap with the Plan footprint. Construction of Alternative 1B water conveyance facilities (CM1) and recreation facilities (CM11) would remove habitat. Habitat enhancement and management activities (CM11) could result in local adverse effects on species. In addition, construction vehicle activity could cause injury or mortality of San Joaquin kit foxes and badgers. Each of these individual activities is described...
below. A summary statement of the combined impacts and NEPA effects and a CEQA conclusion follow the individual conservation measure discussions.

- **CM1 Water Facilities and Operation:** Construction of the conveyance facilities would result in the permanent loss of approximately 172 acres and the temporary loss of 165 acres of modeled San Joaquin kit fox habitat and American badger habitat. This habitat is located in areas of naturalized grassland in a highly disturbed or modified setting on lands immediately adjacent to Clifton Court Forebay, in CZ 8.

- **CM11 Natural Communities Enhancement and Management:** The creation of recreational trails and recreational staging areas would result in the permanent removal of 8 acres of San Joaquin kit fox modeled habitat. AMM 24 would be implemented to ensure that San Joaquin kit fox dens are avoided, as described in BDCP Appendix 3.C, *Avoidance and Minimization Measures.* Passive recreation in the reserve system could result in disturbance of San Joaquin kit foxes at their den site. Natal and pupping dens would be particularly vulnerable to human disturbance. Additionally, disease could be transmitted from domestic dogs that enter the reserve system with recreational users. However, AMM 37 *Recreation* would prohibit construction of new trails within 250 feet of active San Joaquin kit fox dens. Existing trails would be closed within 250 feet of active natal/pupping dens until young have vacated, and within 50 feet of other active dens. No dogs would be allowed on reserve units with active San Joaquin kit fox populations. Rodent control would be prohibited even on grazed or equestrian access areas with San Joaquin kit fox populations. With these restrictions, recreation-related effects on San Joaquin kit fox are expected to be minimal.

The BDCP would require the protection of grasslands in large patch sizes connected to existing large areas of grassland, habitat corridors and transition habitat areas to improve the ecological functions of the grasslands necessary to support the San Joaquin kit fox. American badger is expected to benefit in a similar fashion. The BDCP would require the enhancement and management of these protected existing grasslands and restored grasslands to improve their function as a natural community of plants and wildlife and for associated covered species, including San Joaquin kit fox. The BDCP also includes actions to improve rodent prey availability.

However, management activities could result in injury or mortality of San Joaquin kit fox or American badger if individuals were present in work sites or if dens were located in the vicinity of habitat management work sites. A variety of habitat management actions included in CM11 that are designed to enhance wildlife values on protected lands may result in localized ground disturbances that could temporarily remove small amounts of San Joaquin kit fox and American badger habitat near Clifton Court Forebay, in CZ 8. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, are expected to have minor effects on available habitat and are expected to result in overall improvements to and maintenance of San Joaquin kit fox and badger habitat values over the term of the BDCP. These effects cannot be quantified, but are expected to be minimal and would be avoided and minimized through the AMMs listed below. These AMMs would remain in effect throughout the BDCP's construction phase.

- **Operations and maintenance:** Ongoing maintenance of BDCP facilities would be expected to have little if any adverse effect on San Joaquin kit fox or American badger. Postconstruction operations and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect either species'
use of the surrounding habitat near Clifton Court Forebay, in CZ 8. Maintenance activities would
include vegetation management, levee and structure repair, and regrading of roads and
permanent work areas. These effects, however, would be minimized with implementation of
AMM1–AMM6, AMM10, and AMM24 and with preconstruction surveys for the American badger,
as required by Mitigation Measure BIO-162, Conduct Preconstruction Survey for American
Badger.

- Injury and direct mortality: Water conveyance facility construction may cause injury to or
mortality of either species. If San Joaquin kit fox or American badger reside where activities take
place (most likely in the vicinity of Clifton Court Forebay, in CZ 8), the operation of equipment
for land clearing, construction, operations and maintenance, and restoration, enhancement, and
management activities could result in injury to or mortality of either species. Measures would be
implemented to avoid and minimize injury to or mortality of these species as described in
AMM1–AMM6, AMM10, AMM24, and AMM37 (see BDCP Appendix 3.C) and Mitigation Measure
BIO-162.

The following paragraphs summarize the combined effects discussed above and describe other
BDCP conservation actions that offset or avoid these effects. NEPA effects and a CEQA conclusion are
also included.

**Near-Term Timeframe**

Because water conveyance facilities construction is being evaluated at the project level, the near-
term BDCP strategy has been analyzed to determine whether it would provide sufficient habitat
protection or restoration in an appropriate timeframe to ensure that the construction effects would
not be adverse under NEPA.

Under Alternative 1B there would be a loss of 340 acres of San Joaquin kit fox modeled habitat and
American badger habitat from CM1 (337 acres) and CM11 (3 acres). Typical NEPA project-level
mitigation ratio for the natural community that would be affected and that is identified in the
biological goals and objectives for San Joaquin kit fox in Chapter 3 of the BDCP would be 2:1 for
protection of grassland. Using this ratio would indicate that 680 acres of grassland should be
protected for San Joaquin kit fox to mitigate near-term losses.

The BDCP has committed to near-term restoration of 58 acres of alkali seasonal wetland (Objective
ASWNC1.2), 40 acres of vernal pool complex (Objective VPNC1.2), and 1,140 acres of grassland
(Objective GNC1.2). In addition, there would be near-term protection of 120 acres of alkali seasonal
wetland (Objective ASWNC1.1), 400 acres of vernal pool complex (Objective VPNC1.1), and 2,000
acres of grassland (Objective GNC1.1). The natural community restoration and protection activities
are expected to be concluded during the first 10 years of plan implementation, which is close enough
in time to the occurrence of impacts to constitute adequate mitigation for NEPA purposes. These
commitments are more than sufficient to support the conclusion that the near-term effects of
Alternative 1B would be not be adverse under NEPA, because the number of acres required to meet
the typical ratios described above would be only 680 acres of grassland protected.

The effects on San Joaquin kit fox and American badger habitat from Alternative 1B as a whole
would represent an adverse effect as a result of habitat modification of a special-status species and
potential for direct mortality in the absence of other conservation actions. However, with habitat
protection, restoration associated, and management and enhancement with CM3, CM8, and CM11 in
addition to AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and
Alternative 1B
Terrestrial Biological Resources

Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan,
AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils,
Reusable Tunnel Material, and Dredged Material, AMM10 Restoration of Temporarily Affected Natural
Communities, AMM24 San Joaquin Kit Fox, and AMM37 Recreation, the effects of Alternative 1B on
San Joaquin kit fox and American badger would not be adverse under NEPA. The AMMs include
elements that avoid or minimize the risk of construction activity affecting habitat and species
adjacent to work areas and storage sites. Remaining effects would be addressed by implementation
of Mitigation Measure BIO-162. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance
and Minimization Measures.

Late Long-Term Timeframe

There are 5,327 acres of modeled San Joaquin kit fox habitat in the study area. Alternative 1B as a
whole would result in the permanent loss of and temporary effects on 345 acres of modeled habitat
for San Joaquin kit fox and potential habitat for American badger representing 6% of the modeled
habitat.

With full implementation of the BDCP, at least 1,000 acres of grassland would be protected in CZ 8,
where the San Joaquin kit fox is most likely to occur if present in the Plan Area. Additionally, a
portion of the 2,000 acres of grassland restoration would likely occur in CZ 8. Assuming the restored
grasslands would provide suitable San Joaquin kit fox habitat proportional to the amount of
modeled habitat in this natural community in the Plan Area (6.8% of the grasslands in the Plan Area
consist of modeled San Joaquin kit fox habitat), an estimated 132 acres of restored grasslands would
be suitable for the species. Because San Joaquin kit fox home ranges are large (varying from
approximately 1 to 12 square miles; see BDCP Appendix 2.A, Covered Species Accounts), habitat
connectivity is key to the conservation of the species. Grasslands would be acquired for protection in
locations that provide connectivity to existing protected breeding habitats in CZ 8 (Objective L3.1)
and to other adjoining San Joaquin kit fox habitat within and adjacent to the Plan Area. Connectivity
to occupied habitat adjacent to the Plan Area would help ensure the movement of San Joaquin kit
foxes, if present, to larger habitat patches outside of the Plan Area in Contra Costa County. Grassland
protection would focus in particular on acquiring the largest remaining contiguous patches of
unprotected grassland habitat, which are located south of SR 4 in CZ 8 (BDCP Appendix 2.A, Covered
Species Accounts). This area connects to over 620 acres of existing habitat that was protected under
the East Contra Costa County HCP/NCCP. Grasslands in CZ 8 would also be managed and enhanced
to increase prey availability and to increase mammal burrows, which could benefit the San Joaquin
kit fox by increasing potential den sites, which are a limiting factor for the San Joaquin kit fox in the
northern portion of its range (Objectives ASWNC2.3, ASWNC2.4, VPNC2.4, Objective VPNC2.5,
Objective GNC2.3, and Objective GNC2.4). These management and enhancement actions are
expected to benefit the San Joaquin kit fox as well as the American badger by increasing the habitat
value of the protected and restoration grasslands.

CZ 8 supports 74% of the modeled San Joaquin kit fox grassland habitat in the study area, and the
remainder of habitat consists of fragmented, isolated patches that are unlikely to support this
species. The BDCP’s commitment to protect the largest remaining contiguous habitat patches
(including grasslands and the grassland component of alkali seasonal wetland and vernal pool
complexes) in CZ 8 and to maintain connectivity with the remainder of the satellite population in
Contra Costa County would sufficiently offset the impacts resulting from water conveyance facilities
construction.
The BDCP’s beneficial effects analysis (BDCP Chapter 5, Section 5.6, Effects on Covered Wildlife and Plant Species) estimates that the restoration and protection actions discussed above, as well as the restoration of grassland and vernal pool that could overlap with the species model, would result in the restoration of 131 acres of modeled habitat for San Joaquin kit fox. In addition, protection of grassland and vernal pool complex could overlap with the species model and would result in the protection of 1,011 acres of modeled habitat for San Joaquin kit fox.

**NEPA Effects:** In the absence of other conservation actions, the effects on San Joaquin kit fox and American badger habitat from Alternative 1B would represent an adverse effect as a result of habitat modification and potential direct mortality of special-status species. However, with habitat protection, restoration, management, and enhancement associated with CM3, CM8, and CM11, and guided by AMM1–AMM6, AMM10, AMM24, AMM37, which would be in place throughout the time period of construction, and with implementation of Mitigation Measure BIO-162, **Conduct Preconstruction Survey for American Badger,** the effects of Alternative 1B as a whole on San Joaquin kit fox and American badger would not be adverse under NEPA.

**CEQA Conclusion:**

**Near-Term Timeframe**

Because water conveyance facilities construction (CM1) is being evaluated at the project level, the near-term BDCP strategy has been analyzed to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the construction effects would be less than significant for CEQA purposes.

Under Alternative 1B there would be a loss of 340 acres of San Joaquin kit fox modeled habitat and American badger habitat from CM1 (337 acres) and CM11 (3 acres). Typical NEPA project-level mitigation ratio for the natural community that would be affected and that is identified in the biological goals and objectives for San Joaquin kit fox in Chapter 3 of the BDCP would be 2:1 for protection of grassland. Using this ratio would indicate that 680 acres of grassland should be protected for San Joaquin kit fox to mitigate near-term losses.

The BDCP has committed to near-term restoration of 58 acres of alkali seasonal wetland (Objective ASWNC1.2), 40 acres of vernal pool complex (Objective VPNC1.2), and 1,140 acres of grassland (Objective GNC1.2). In addition, there would be near-term protection of 120 acres of alkali seasonal wetland (Objective ASWNC1.1), 400 acres of vernal pool complex (Objective VPNC1.1), and 2,000 acres of grassland (Objective GNC1.1).

These conservation actions would occur in the same timeframe as the construction losses, thereby avoiding adverse effects of habitat loss on San Joaquin kit fox and American badger. These Plan objectives represent performance standards for considering the effectiveness of CM3 protection and restoration actions. The acres of restoration and protection contained in the near-term Plan goals and the additional detail in the biological objectives for San Joaquin kit fox and the mitigation measure for American badger satisfy the typical mitigation that would be applied to the project-level effects of CM1, as well as mitigate the near-term effects of the other conservation measures.

The BDCP also contains commitments to implement AMM1–AMM6, AMM10, AMM24, and AMM37 which include elements that avoid or minimize the risk of construction activity impacting habitat and species adjacent to work areas. Remaining effects would be addressed by implementation of Mitigation Measure BIO-162. The AMMs are described in detail in BDCP Appendix 3.C, **Avoidance and Minimization Measures.**
These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 1B on San Joaquin kit fox and American badger would be less than significant under CEQA, because the number of acres required to meet the typical ratios described above would be only 680 acres of grassland protected.

**Late Long-Term Timeframe**

There are 5,327 acres of modeled San Joaquin kit fox habitat in the study area. Alternative 1B as a whole would result in the permanent loss of and temporary effects on 345 acres of modeled habitat for San Joaquin kit fox and potential habitat for American badger representing 6% of the modeled habitat.

With full implementation of Alternative 1B, at least 1,000 acres of grassland would be protected in CZ 8, where the San Joaquin kit fox is most likely to occur if present in the Plan Area. Additionally, a portion of the 2,000 acres of grassland restoration would likely occur in CZ 8. Assuming the restored grasslands would provide suitable San Joaquin kit fox habitat proportional to the amount of modeled habitat in this natural community in the Plan Area (6.8% of the grasslands in the Plan Area consist of modeled San Joaquin kit fox habitat), an estimated 132 acres of restored grasslands would be suitable for the species (6.6% of 2,000 acres). Because San Joaquin kit fox home ranges are large (ranging from around 1 to 12 square miles; see BDCP Appendix 2.A, Covered Species Accounts), habitat connectivity is key to the conservation of the species. Grasslands would be acquired for protection in locations that provide connectivity to existing protected breeding habitats in CZ 8 (Objective L3.1) and to other adjoining San Joaquin kit fox habitat within and adjacent to the Plan Area. Connectivity to occupied habitat adjacent to the Plan Area would help ensure the movement of San Joaquin kit foxes, if present, to larger habitat patches outside of the Plan Area in Contra Costa County. Grassland protection would focus in particular on acquiring the largest remaining contiguous patches of unprotected grassland habitat, which are located south of SR 4 in CZ 8 (BDCP Appendix 2.A). This area connects to over 620 acres of existing habitat that was protected under the East Contra Costa County HCP/NCCP. Grasslands in CZ 8 would also be managed and enhanced to increase prey availability and to increase mammal burrows, which could benefit the San Joaquin kit fox by increasing potential den sites, which are a limiting factor for the San Joaquin kit fox in the northern portion of its range (Objectives ASWNC2.3, ASWNC2.4, VPC2.4, Objective VPC2.5, Objective GNC2.3, and Objective GNC2.4). These management and enhancement actions are expected to benefit the San Joaquin kit fox as well as the American badger by increasing the habitat value of the protected and restoration grasslands.

CZ 8 supports 74% of the modeled San Joaquin kit fox grassland habitat in the study area, and the remainder of habitat consists of fragmented, isolated patches that are unlikely to support this species. The BDCP’s commitment to protect the largest remaining contiguous habitat patches (including grasslands and the grassland component of alkali seasonal wetland and vernal pool complexes) in CZ 8 and to maintain connectivity with the remainder of the satellite population in Contra Costa County would sufficiently offset the impacts resulting from water conveyance facilities construction.

The BDCP’s beneficial effects analysis (BDCP Chapter 5, Section 5.6, Effects on Covered Wildlife and Plant Species) estimates that the restoration and protection actions discussed above, as well as the restoration of grassland and vernal pool that could overlap with the species model, would result in the restoration of 131 acres of modeled habitat for San Joaquin kit fox. In addition, protection of
grassland and vernal pool complex could overlap with the species model and would result in the protection of 1,011 acres of modeled habitat for San Joaquin kit fox.

In the absence of other conservation actions, the effects on San Joaquin kit fox and American badger habitat from Alternative 1B would represent an adverse effect as a result of habitat modification and potential direct mortality of special-status species. However, with habitat protection, restoration, management, and enhancement associated with CM3, CM8, and CM11, and guided by AMM1–AMM6, AMM10, AMM24, and AMM37, which would be in place throughout the time period of construction, and with implementation of Mitigation Measure BIO-162, the impact of Alternative 1B as a whole on San Joaquin kit fox and American badger would not be significant under CEQA.

**Mitigation Measure BIO-162: Conduct Preconstruction Survey for American Badger**

A qualified biologist provided by DWR will survey for American badger concurrent with the preconstruction survey for San Joaquin kit fox and burrowing owl. If badgers are detected, the biologist will passively relocate badgers out of the work area prior to construction if feasible. If an active den is detected within the work area, DWR will avoid the den until the qualified biologist determines the den is no longer active. Dens that are determined to be inactive by the qualified biologist will be collapsed by hand to prevent occupation of the den between the time of the survey and construction activities.

**Impact BIO-163: Indirect Effects of Plan Implementation on San Joaquin Kit Fox and American Badger**

Noise and visual disturbances outside the project footprint but within 250 feet of construction activities could temporarily affect modeled San Joaquin kit fox habitat and potential American badger habitat. Water conveyance facilities operations and maintenance activities would include vegetation and weed control, ground squirrel control, canal maintenance, infrastructure and road maintenance, levee maintenance, and maintenance and upgrade of electrical systems. While maintenance activities are not expected to remove San Joaquin kit fox and badger habitat, operation of equipment could disturb small areas of vegetation around maintained structures and could result in injury or mortality of individual foxes and badgers, if present. Given the remote likelihood of active San Joaquin kit fox or badger dens in the vicinity of the conveyance facilities, the potential for this effect is small and would further be minimized with the implementation of seasonal no-disturbance buffers around occupied dens, and implementation of other measures as described in AMM1–AMM6, AMM10, AMM24, and AMM37 and Mitigation Measure BIO-162.

**NEPA Effects:** Implementation of the AMMs listed above and Mitigation Measure BIO-162, *Conduct Preconstruction Survey for American Badger*, would avoid the potential for substantial adverse effects on San Joaquin kit fox or American badger, either indirectly or through habitat modifications. These measures would also avoid and minimize effects that could substantially reduce the number of San Joaquin kit fox or American badger, or restrict either species’ range. Therefore, the indirect effects of Alternative 1B would not have an adverse effect on San Joaquin kit fox or American badger.

**CEQA Conclusion:** Indirect effects from conservation measure operations and maintenance as well as construction-related noise and visual disturbances could impact San Joaquin kit fox and American badger. With implementation of AMM1–AMM6, AMM10, AMM24, and AMM37 as part of Alternative 1B construction, operation, and maintenance, the BDCP would avoid the potential for significant adverse effects on either species, either indirectly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of either species. In...
addition, Mitigation Measure BIO-162 would reduce the impact of indirect effects of Alternative 1B on American badger to a less-than-significant level.

**Mitigation Measure BIO-162: Conduct Preconstruction Survey for American Badger**

Please see Mitigation Measure BIO-162 under Impact BIO-162.

San Joaquin Pocket Mouse

This section describes the effects of Alternative 1B, including water conveyance facilities construction and implementation of other conservation components, on San Joaquin pocket mouse. Habitat for this species consists of the grassland natural community throughout the Plan Area. The species requires friable soils for burrowing.

Construction and restoration associated with Alternative 1B conservation measures would result in both temporary and permanent losses of San Joaquin pocket mouse habitat as indicated in Table 12-1B-60. Full implementation of Alternative 1B would also include the following conservation actions over the term of the BDCP that would likely benefit San Joaquin pocket mouse.

- Protect at least 8,000 acres of grasslands (Objective GNC1.1, associated with CM3).
- Restore at least 2,000 acres of grasslands to connect fragmented patches of protected grasslands (Objective GNC1.2, associated with CM8).
- Restore and sustain a mosaic of grassland vegetation alliances, reflecting localized water availability, soil chemistry, soil texture, topography, and disturbance regimes, with consideration of historical states (Objective GNC2.1).

As explained below, with the restoration or protection of these amounts of habitat, impacts on San Joaquin pocket mouse would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

\(^a\) See Appendix 12E for detailed breakdown of conservation measure effects over the BDCP’s near-term and late long-term timeframes.

\(^b\) See discussion below for a description of applicable CMs.

\(^c\) LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

\(^d\) Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as a range based on different flow regimes at the proposed notch in Fremont Weir.

Impact BIO-164: Loss or Conversion of Habitat for and Direct Mortality of San Joaquin Pocket Mouse

Alternative 1B conservation measures would result in the combined permanent and temporary loss of up to 3,209 acres of habitat for San Joaquin pocket mouse (of which 2,654 acres would be a permanent loss and 555 acres would be a temporary loss of habitat, Table 12-1B-60). Conservation measures that would result in these losses are conveyance facilities and transmission line construction, and establishment and use of borrow and spoil areas (CM1), Yolo Bypass Fisheries Enhancement (CM2), Tidal Natural Communities Restoration (CM4), Seasonally Inundated Floodplain Restoration (CM5), Grassland Natural Community Restoration (CM8), Vernal Pool Natural Community and Alkali Seasonal Wetland Complex Restoration (CM9), Nontidal Marsh Restoration (CM10), and Conservation Hatcheries (CM18). The majority of habitat loss would result from CM4. Habitat enhancement and management activities (CM11), which include ground disturbance or removal of nonnative vegetation, could result in local adverse habitat effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could degrade or eliminate San Joaquin pocket mouse habitat. Each of these individual activities is described below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- **CM1 Water Facilities and Operation:** Construction of Alternative 1B conveyance facilities would result in the combined permanent and temporary loss of up to 761 acres of potential San Joaquin pocket mouse habitat (403 acres of permanent loss, 358 acres of temporary loss) in CZ 3–CZ 6, CZ 8, and CZ 9. The majority of grassland that would be removed would be in CZ 8 and CZ 9, from the construction of the new canals. Refer to the Terrestrial Biology Map Book for a detailed view of Alternative 1B construction locations. Construction of the forebay would affect...
the area where there is a record of San Joaquin pocket mouse (California Department of Fish and Wildlife 2013).

- **CM2 Yolo Bypass Fisheries Enhancement:** Construction of the Yolo bypass fisheries enhancement (CM2) would permanently remove 261 acres of potential San Joaquin pocket mouse habitat in the Yolo Bypass in CZ 2. In addition, 165 acres would be temporarily removed. Most of the grassland losses would occur at the north end of the bypass below Fremont Weir, along the Toe Drain/Tule Canal, and along the west side channels.

- **CM4 Tidal Natural Communities Restoration:** Tidal habitat restoration (CM4) site preparation and inundation would permanently remove an estimated 1,506 acres of potential San Joaquin pocket mouse habitat. The majority of the losses would likely occur in the vicinity of Cache Slough, on Decker Island in the West Delta ROA, on the upslope fringes of Suisun Marsh, and along narrow bands adjacent to waterways in the South Delta ROA. Tidal restoration would directly impact and fragment remaining grassland just north of Rio Vista in and around French and Prospect Islands, and in an area south of Rio Vista around Three mile Slough.

- **CM5 Seasonally Inundated Floodplain Restoration:** Construction of setback levees to restore seasonally inundated floodplain (CM5) would permanently and temporarily remove approximately 481 acres of San Joaquin pocket mouse habitat (449 permanent, 32 temporary). These losses would be expected to occur along the San Joaquin River and other major waterways in CZ 7.

- **CM8 Grassland Natural Community Restoration and CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration:** Temporary construction-related disturbance of grassland habitat would result from implementation of CM8 and CM9 in CZ 1, CZ 8, and CZ 11. However, all areas would be restored to their original or higher value habitat after the construction periods. The resulting restoration of 2,000 acres of grassland would benefit San Joaquin pocket mouse.

- **CM11 Natural Communities Enhancement and Management:** The protection of 8,000 acres of grassland for covered species is also expected to benefit San Joaquin pocket mouse by protecting existing habitats from potential loss or degradation that otherwise could occur with future changes in existing land use. Habitat management and enhancement-related activities could cause disturbance or direct mortality to San Joaquin pocket mouse if they are present near work areas.

A variety of habitat management actions included in CM11 Natural Communities Enhancement and Management that are designed to enhance wildlife values in restored or protected habitats could result in localized ground disturbances that could temporarily remove small amounts of San Joaquin pocket mouse habitat. Ground-disturbing activities, such as removal of nonnative vegetation and road and other infrastructure maintenance activities, would be expected to have minor adverse effects on habitat and would be expected to result in overall improvements to and maintenance of habitat values over the term of the BDCP. Noise and visual disturbance from management-related equipment operation could temporarily displace individuals or alter the behavior of the species if adjacent to work areas. With full implementation of the BDCP, enhancement and management actions designed for western burrowing owl would also be expected to benefit these species. San Joaquin pocket mouse would benefit particularly from protection of grassland habitat against potential loss or degradation that otherwise could occur with future changes in existing land use.
• **CM18 Conservation Hatcheries**: Implementation of CM18 would remove up to 35 acres of San Joaquin pocket mouse habitat.

• **Operations and Maintenance**: Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect San Joaquin pocket mouse use of the surrounding habitat. Maintenance activities would include vegetation management, levee and structure repair, and re-grading of roads and permanent work areas. These effects, however, would be reduced by AMMs and conservation actions as described below.

• **Injury and Direct Mortality**: Construction could result in direct mortality of San Joaquin pocket mouse if present in construction areas.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA and CEQA impact conclusions are also included.

**Near-Term Timeframe**

Because the water conveyance facility construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the effects of such conveyance facility construction would not be adverse under NEPA. Alternative 1B would remove 1,877 acres of San Joaquin pocket mouse habitat (1,354 permanent, 523 temporary) in the study area in the near-term. One record of San Joaquin pocket mouse near Clifton Court forebay could be affected by the construction of the new forebay. These effects would result from the construction of the water conveyance facilities (CM1, 761 acres), and implementing other conservation measures (Yolo Bypass Fisheries Enhancement [CM2], Tidal Natural Communities Restoration [CM4], Seasonally Inundated Floodplain Restoration [CM5], Grassland Natural Community Restoration [CM8], Vernal Pool and Alkali Seasonal Wetland Complex Restoration [CM9], and Conservation Hatcheries [CM18] 1,116 acres).

Typical NEPA project-level mitigation ratios for those natural communities affected by CM1 would be 2:1 protection of grassland habitat. Using these typical ratios would indicate that 1,522 acres of grassland natural communities should be protected to mitigate the CM1 permanent and temporary effects on 751 acres of San Joaquin pocket mouse habitat. The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community in CZ 1, CZ 2, CZ 4, CZ 5, CZ 7, CZ 8, and CZ 11. The protection and restoration of grasslands, would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand habitat for San Joaquin pocket mouse and reduce the effects of current levels of habitat fragmentation. Under **CM11 Natural Communities Enhancement and Management**, San Joaquin pocket mouse would likely benefit from the management of the grasslands for general wildlife benefit.

These natural community biological goals and objectives would inform the near-term protection and restoration efforts and represent performance standards for considering the effectiveness of restoration actions for the species. The acres of protection and restoration contained in the near-term Plan goals would satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1, especially considering that a large portion of the affected grasslands consists of thin
Alternative 1B
Terrestrial Biological Resources

strips of grassland along levees and that areas of grassland protection and restoration would be in large contiguous blocks.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM10 Restoration of Temporarily Affected Natural Communities. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas and storage sites. The AMMs are described in detail in BDCP Appendix 3.C.

Late Long-Term Timeframe

Based on the habitat model, the study area supports approximately 78,624 acres of potential habitat for San Joaquin pocket mouse. Alternative 1B as a whole would result in the permanent loss of and temporary effects on 3,209 acres of grasslands that could be suitable for San Joaquin pocket mouse (4% of the habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes a commitment to restore or create at least 2,000 acres of grassland in CZ 1, CZ 8 and CZ 11 and to protect 8,000 acres of grassland (with at least 2,000 acres protected in CZ 1, at least 1,000 acres in CZ 8, at least 2,000 acres protected in CZ 11, and the remainder distributed throughout CZ 1, CZ 2, CZ 4, CZ 5, CZ 7, CZ 8, and CZ 11 in the study area. All protected habitat would be managed under CM11 Natural Communities Enhancement and Management.

NEPA Effects: In the absence of other conservation actions, the loss of San Joaquin pocket mouse habitat associated with Alternative 1B would represent an adverse effect as a result of habitat modification and potential mortality of a special-status species. However, with habitat protection and restoration associated with CM3, CM8, and CM11, guided by biological goals and objectives and by AMM1–AMM6, and AMM10 which would be in place throughout the construction period, the effects of habitat loss and potential mortality under Alternative 1B on San Joaquin pocket mouse would not be adverse.

CEQA Conclusion: Alternative 1B (CM1–CM5, and CM11) would have both temporary and permanent impacts on San Joaquin pocket mouse and its habitat and operation of construction equipment could disturb individuals, if present in the study area.

Near-Term Timeframe

Because the water conveyance facility construction is being evaluated at the project level, the near-term BDCP conservation strategy has been evaluated to determine whether it would provide sufficient habitat protection and/or restoration in an appropriate timeframe to ensure that the effects of such conveyance facility construction would be less than significant under CEQA. Alternative 1B would remove 1,877 acres of modeled (1,354 permanent, 523 temporary) habitat for San Joaquin pocket mouse in the study area in the near-term. One record of San Joaquin pocket mouse near Clifton Court forebay could be affected by the construction of the new forebay. These effects would result from the construction of the water conveyance facilities (CM1, 761 acres), and implementing other conservation measures (CM2 Yolo Bypass Fisheries Enhancement, CM4 Tidal Natural Communities Restoration, CM5 Seasonally Inundated Floodplain Restoration, CM6 Grassland Natural Community Restoration, CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration, and CM18 Conservation Hatcheries—1,116 acres).
Typical CEQA project-level mitigation ratios for those natural communities affected by CM1 would be 2:1 protection of grassland habitat. Using these typical ratios would indicate that 1,522 acres of grassland natural communities should be protected to mitigate the CM1 losses of 645 acres of San Joaquin pocket mouse habitat.

The BDCP has committed to near-term goals of protecting 2,000 acres and restoring 1,140 acres of grassland natural community in CZ 1, CZ 2, CZ 4, CZ 5, CZ 7, CZ 8, and CZ 11. The protection and restoration of grasslands, would result in a contiguous matrix of grassland, alkali seasonal wetland, and vernal pool natural communities which would expand habitat for San Joaquin pocket mouse and reduce the effects of current levels of habitat fragmentation. Under CM11 Natural Communities Enhancement and Management, San Joaquin pocket mouse would likely benefit from the management of the grasslands for general wildlife benefit.

These natural community biological goals and objectives would inform the near-term protection and restoration efforts and represent performance standards for considering the effectiveness of restoration actions for the species. The acres of protection and restoration contained in the near-term Plan goals would satisfy the typical mitigation ratios that would be applied to the project-level effects of CM1, especially considering that a large portion of the affected grasslands consists of thin strips of grassland along levees and that areas of grassland protection and restoration would be in large contiguous blocks.

The Plan also includes commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM10 Restoration of Temporarily Affected Natural Communities. All of these AMMs include elements that avoid or minimize the risk of affecting habitats and species adjacent to work areas and storage sites. The AMMs are described in detail in BDCP Appendix 3.C.

These commitments are more than sufficient to support the conclusion that the near-term effects of Alternative 1B would be less than significant under CEQA.

Late Long-Term Timeframe

Based on the habitat model, the study area supports approximately 78,624 acres of potential habitat for San Joaquin pocket mouse. Alternative 1B as a whole would result in the permanent loss of and temporary effects on 3,209 acres of grasslands that could be suitable for San Joaquin pocket mouse (4% of the habitat in the study area). The locations of these losses are described above in the analyses of individual conservation measures. The Plan includes a commitment to restore or create at least 2,000 acres of grassland in CZ 1, CZ 8 and CZ 11 and to protect 8,000 acres of grassland (with at least 2,000 acres protected in CZ 1, at least 1,000 acres in CZ 8, at least 2,000 acres protected in CZ 11, and the remainder distributed throughout CZ 1, CZ 2, CZ 4, CZ 5, CZ 7, CZ 8, and CZ 11 in the study area. All protected habitat would be managed under CM11 Natural Communities Enhancement and Management.

Considering these protection and restoration provisions, which would provide acreages of new high-value or enhanced habitat in amounts suitable to compensate for habitats lost to construction and restoration activities, and with implementation of AMM1–AMM6, and AMM10, the loss of habitat or direct mortality through implementation of Alternative 1B would not result in a substantial adverse effect through habitat modifications and would not substantially reduce the
number or restrict the range of San Joaquin pocket mouse. Therefore, the loss of habitat or potential mortality under this alternative would have a less-than-significant impact on San Joaquin pocket mouse.

**Impact BIO-165: Indirect Effects of Plan Implementation on San Joaquin Pocket Mouse**

Construction activities associated with water conveyance facilities, conservation components and ongoing habitat enhancement, as well as operations and maintenance of above-ground water conveyance facilities, including the transmission facilities, could result in ongoing periodic postconstruction disturbances and noise with localized effects on San Joaquin kit pocket mouse and its habitat over the term of the BDCP. These potential effects would be minimized and avoided through AMM1–AMM6, and AMM10, which would be in effect throughout the plan’s construction phase.

Water conveyance facilities operations and maintenance activities would include vegetation and weed control, ground squirrel control, canal maintenance, infrastructure and road maintenance, levee maintenance, and maintenance and upgrade of electrical systems. While maintenance activities are not expected to remove pocket mouse habitat, operation of equipment could disturb small areas of vegetation around maintained structures and could result in injury or mortality of individual pocket mice, if present.

**NEPA Effects:** Implementation of the AMMs listed above would avoid the potential for substantial adverse effects on San Joaquin pocket mouse, either indirectly or through habitat modifications. These measures would also avoid and minimize effects that could substantially reduce the number of San Joaquin pocket mouse, or restrict the species’ range. Therefore, the indirect effects of Alternative 1B would not have an adverse effect on San Joaquin pocket mouse.

**CEQA Conclusion:** Indirect effects from conservation measure operations and maintenance as well as construction-related noise and visual disturbances could impact San Joaquin pocket mouse. With implementation of AMM1–AMM6, and AMM10, as part of Alternative 1B construction, operation, and maintenance, the BDCP would avoid the potential for significant adverse effects on either species, either indirectly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of the species. Therefore, the indirect effects under this alternative would have a less-than-significant impact on San Joaquin pocket mouse.

**Special-Status Bat Species**

Special-status bat species with potential to occur in the study area employ varied roost strategies, from solitary roosting in foliage of trees to colonial roosting in trees and artificial structures, such as tunnels, buildings, and bridges. Various roost strategies could include night roosts, maternity roosts, migration stopover, or hibernation. The habitat types used to assess effects for special-status bats roosting habitat includes valley/foothill riparian natural community, developed lands and landscaped trees, including eucalyptus, palms and orchards. Potential foraging habitat includes all riparian habitat types, cultivated lands, developed lands, grasslands, and wetlands.

There is potential for at least thirteen different bat species to be present in the study area (Figure 12-51), including four California species of special concern and nine species ranked from low to moderate priority by the Western Bat Working Group (Table 12A-2 in Appendix 12A, Special-Status Species with Potential to Occur in the Study Area). In 2009, DHCCP conducted a large-scale effort that involved habitat assessments, bridge surveys, and passive acoustic monitoring surveys for bats (see...
Appendix 12C, 2009 to 2011 Bay Delta Conservation Plan EIR/EIS Environmental Data Report for
details on methods and results, and Table 12A-2 in Appendix 12A).

The majority of the parcels assessed during field surveys contained bat foraging and roosting
features and were considered highly suitable habitat. At the time of the 2009 field surveys, DWR
biologists initially identified 145 bridges in their survey area. Eleven of the 145 bridges were not
accessible and thirteen were determined to not be suitable for bats. Evidence of bat presence was
observed at six of the bridges and bat sign (guano, urine staining, odor, or vocalizations) was
observed at 26 of the bridges. Biologists observed Mexican free-tailed bats at four of the bridges and
unidentified species at the remaining two bridges. One of these bridges, over the Yolo Causeway,
was used by approximately 10,000 Mexican free-tailed bats, indicating a maternity roost. A second
roost site of about 50 individuals was observed under a bridge in eastern Solano County.

The remaining 89 bridges contained structural features that were considered conducive to
maternity, solitary, day and/or night roosting. Night roosts may have crevices and cracks but more
often have box beams or other less protected roosting spots where bats rest temporarily while
feeding. Day roosts are commonly found in bridges with expansion joints, crevices, or cracks where
bats are protected from predators and weather. Seventeen bridges in the survey area had no
potential for roosting because they lacked surface features from which bats could hang and offered
no protection from weather or predators.

Construction and restoration associated with Alternative 1B conservation measures would result in
both temporary and permanent losses of foraging and roosting habitat for special-status bats as
indicated in Table 12-1B-61. Protection and restoration for special-status bat species focuses on
habitats and does not include manmade structures such as bridges. The conservation measures that
would be implemented to achieve the biological goals and objectives that would also benefit special-
status bats are summarized below.

- Protect or restore 142,200 acres of high-value natural communities (Objective L1.1, associated
  with CM3). This objective includes protecting and restoring a variety of habitat types described
  below (BDCP Chapter 3, Table 3.3-2).
  - Protect 150 acres of alkali seasonal wetland in CZ 1, CZ 8, and/or CZ 11 among a mosaic of
    protected grasslands and vernal pool complex (Objective ASWNC1.1, associated with CM3).
  - Protect 600 acres of existing vernal pool complex (Objective VPNC1.1, associated with CM3).
  - Protect 8,000 acres of grassland (Objective GNC1.1, associated with CM3).
  - Protect 8,100 acres of managed wetland (Objective MWNC1.1, associated with CM3 and
    CM11).
  - Protect 48,625 acres of cultivated lands (Objective CLNC1.1, associated with CM3 and
    CM11).
  - Protect, restore, or create 2,740 acres of rice land or equivalent habitat type for the giant
garter snake (Objective GGS3.1, associated with CM3, CM4, and CM10).
  - Restore 2,000 acres of grasslands to connect fragmented patches of protected (Objective
    GNC1.2, associated with CM3 and 8).
  - Restore 67 acres of vernal pool complex (Objective VPNC1.2, associated with CM3 and 9).
- Restore and protect 65,000 acres of tidal natural communities (Objective L1.2, associated with CM2, 3, and 4).
- Restore or create 5,000 acres of valley/foothill riparian natural community (Objective VFRNC1.1, associated with CM3 and CM7).
- Protect 750 acres of existing valley/foothill riparian natural community in CZ 7 by year 10 (Objective VFRNC1.2, associated with CM3).

As explained below, with the restoration and protection of these amounts of habitat, in addition to mitigation measures to reduce potential effects, impacts on special-status bats would not be adverse for NEPA purposes and would be less than significant for CEQA purposes.

<sup>a</sup> See Appendix 12E for detailed breakdown of conservation measure effects over the BDCP's near-term and late long-term timeframes.

<sup>b</sup> See discussion below for a description of applicable CMs.

<sup>c</sup> Affected roosting habitat acreages include valley/foothill riparian habitat and orchards. An unknown number of buildings, bridges, tunnels, and individual trees could also be affected but were not included in this analysis. Foraging habitat includes all natural communities, cultivated lands, and developed lands in the study area. Foraging habitat effects for CM2-CM18 were not considered adverse as they reflect a conversion from one foraging habitat type (mostly cultivated lands) to another foraging habitat (wetlands).

<sup>d</sup> LLT acreages are a summation of effects that would occur in the near-term, early long-term and late long-term timeframes. The LLT acreages represent the total amount of habitat that would be affected over the 50-year life of the BDCP and do not reflect habitat increases that would result from restoration, creation and protection activities.

<sup>e</sup> Periodic effects were estimated for the late long-term only. CM2 periodic impacts are presented as the maximum possible based on different flow regimes at the proposed notch in Fremont Weir.

**Impact BIO-166: Loss or Conversion of Habitat for and Direct Mortality of Special-Status Bats**

Alternative 1B conservation measure CM1 would result in the permanent and temporary loss of up to 796 acres of roosting habitat and 21,827 acres of foraging habitat for special-status bats in the study area. DWR identified three bridges as potential night roosting that could be affected by construction in CM1. Conservation measures Fremont Weir/Yolo Bypass improvements...
Alternative 1B
Terrestrial Biological Resources

(CM2), tidal habitat restoration (CM4), and floodplain restoration (CM5) would result in the permanent and temporary loss of 1,782 acres of roosting habitat and the conversion of approximately 65,525 acres of foraging habitat from mostly cultivated lands and managed wetlands to tidal and nontidal wetlands. Foraging habitat effects for CM2-CM18 were not considered adverse as they reflect a conversion from one foraging habitat type (mostly cultivated lands) to another foraging habitat (wetlands). Habitat enhancement and management activities (CM11) could result in local adverse effects. In addition, maintenance activities associated with the long-term operation of the water conveyance facilities and other BDCP physical facilities could affect special-status bat habitat. A summary of combined impacts and NEPA effects and a CEQA conclusion follow the individual conservation measure discussions.

- **CM1 Water Facilities and Operation**: Construction of Alternative 1B conveyance facilities would result in the permanent loss of approximately 474 acres of roosting habitat and 8,572 acres of foraging habitat in the study area. Development of the water conveyance facilities would also result in the temporary removal of up to 322 acres of roosting habitat and up to 13,255 acres of foraging habitat for special-status bats in the study area (Table 12-1B-61). DWR identified three bridges with potential night roosting habitat for bats; one is in a new bridge construction area, the other two are within the railroad work area that could be affected by construction for CM1.

- **CM2 Yolo Bypass Fisheries Enhancement**: Improvements in the Yolo Bypass would result in the conversion of approximately 2,025 acres of foraging habitat into wetlands that could still be used by bats for foraging. CM2 would also result in the permanent removal of 89 acres and temporary removal of 167 acres of roosting habitat for special-status bats. The maternity colony of Mexican free-tailed bats located at both ends of the Yolo Causeway bridge could also be affected during construction for CM2. Implementation of Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*, would ensure that improvements in the Yolo Bypass avoid effects on roosting special-status bats.

- **CM4 Tidal Natural Communities Restoration**: Tidal habitat restoration site preparation and inundation would result in the conversion of approximately 56,810 acres of foraging habitat into wetlands that could still be used by bats for foraging. Approximately 1,425 acres of roosting habitat for special-status bats would permanently affected. This habitat is of low value, consisting of a small, isolated patch surrounded by cultivated lands, and the species has a relatively low likelihood of being present in these areas. The roosting habitat that would be removed consists of relatively small and isolated patches along canals and irrigation ditches surrounded by cultivated lands in the Union Island and Roberts Island areas, and several small patches along the San Joaquin River. Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*, described below, requires that tidal natural communities restoration avoid effects on roosting special-status bats.

- **CM5 Seasonally Inundated Floodplain Restoration**: Levee construction associated with floodplain restoration would result in the conversion of an estimated 3,690 acres of foraging habitat into wetlands that could still be used by bats for foraging. CM5 would also result in the permanent removal of 57 acres and temporary removal of 45 acres of roosting habitat for special-status bats in the study area.

- **CM11 Natural Communities Enhancement and Management**: Implementation of Alternative 1B would result in an overall benefit to special-status bats within the study area through protection and restoration of their foraging and roosting habitats. The majority of affected acres would convert agricultural land to natural communities with higher potential foraging and roosting.
value, such as riparian, tidal and nontidal wetlands, and periodically inundated lands. Implementation of Restored foraging habitats primarily would replace agricultural lands. Restored habitats are expected to be of higher function because the production of flying insect prey species is expected to be greater in restored wetlands and uplands on which application of pesticides would be reduced relative to affected agricultural habitats. Noise and visual disturbances during implementation of riparian habitat management actions could result in temporary disturbances that, if bat roost sites are present, could cause temporary abandonment of roosts. This effect would be minimized with implementation of Mitigation Measure BIO-166, Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures.

- Operations and maintenance: Ongoing facilities operation and maintenance is expected to have little if any adverse effect on special-status bats. Postconstruction operation and maintenance of the above-ground water conveyance facilities and restoration infrastructure could result in ongoing but periodic disturbances that could affect special-status bat use of the surrounding habitat in the Yolo Bypass, the Cache Slough area, and the north and south Delta (CZ 1, CZ 2, CZ 4, CZ 5, CZ 6, CZ 7 and CZ 8). Maintenance activities would include vegetation management, levee and structure repair, and regrading of roads and permanent work areas. These effects, however, would be minimized with implementation of the mitigation measure described below.

- Injury and direct mortality: In addition, to habitat loss and conversion, construction activities, such as grading, the movement of construction vehicles or heavy equipment, and the installation of water conveyance facilities components and new transmission lines, may result in the direct mortality, injury, or harassment of roosting special-status bats. Construction activities related to conservation components could have similar affects. Preconstruction surveys would be conducted and if roosting or maternity sites are detected, seasonal restrictions would be placed while bats are present, as described below in the mitigation measure.

The following paragraphs summarize the combined effects discussed above and describe other BDCP conservation actions that offset or avoid these effects. NEPA effects and CEQA conclusions are also included.

**Near-Term Timeframe**

Because water conveyance facilities construction is being evaluated at the project level, the near-term BDCP strategy has been analyzed to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the construction effects would not be adverse under NEPA. Because the majority of affected acres would convert agricultural land to natural communities with higher potential foraging and roosting value, such as riparian, tidal and nontidal wetlands, and periodically inundated lands this analysis focuses only on losses of roosting habitat under CM1, CM2, and CM4.

Alternative 1B would permanently or temporarily affect 1,487 acres of roosting habitat for special-status bats in the near-term as a result of implementing CM1 (796 acres roosting habitat), CM2 (256 acres roosting habitat), and CM4 (435 acres roosting habitat). Effects from CM5 would all occur in the late long-term. Most of the roosting habitat losses would occur in the valley/foothill riparian natural community.

Typical NEPA project-level mitigation ratios for those natural communities that would be affected for roosting habitat would be 1:1 for restoration and protection of the valley/foothill riparian
natural community. Using these ratios would indicate that 1,487 acres of riparian habitat should be restored and 1,487 acres of riparian habitat should be protected.

Implementation of BDCP actions in the near-term would result in an overall benefit to special-status bats within the study area through protection and restoration of their foraging and roosting habitats (Objective L1.1). BDCP actions in the near-term would restore 800 acres of riparian roosting and foraging habitat (Objective VFRNC1.1) and 21,288 acres of foraging habitat in natural communities and developed lands (Objective L1.1, Objective GNC1.2, Objective VPNC1.2, Objective L1.2, and Objective L2.11). In addition, the BDCP would protect 750 acres of riparian roosting and foraging habitat (Objective VFRNC1.2) and 41,445 acres of foraging habitat (Objective L1.1, Objective ASWNC1.1, Objective VPRNC1.1, Objective MWNC1.1, Objective CLNC1.1, Objective GGS3.1, and Objective GNC1.1). Restored foraging habitats would replace primarily cultivated lands. Restored habitats are expected to be of higher function because the production of flying insect prey species is expected to be greater in restored wetlands and uplands on which application of pesticides would be reduced relative to affected agricultural habitats. Conservation components in the near-term would sufficiently offset the adverse effects resulting from near-term effects from Alternative 1B.

In addition, activities associated with natural communities enhancement and protection and with ongoing facilities operations and maintenance could affect special-status bat use of surrounding habitat and could result in harassment, injury or mortality of bats. Mitigation Measure BIO-166, described below, requires preconstruction surveys to reduce these effects.

The BDCP also contains commitments to implement AMM1 Worker Awareness Training, AMM2 Construction Best Management Practices and Monitoring, AMM3 Stormwater Pollution Prevention Plan, AMM4 Erosion and Sediment Control Plan, AMM5 Spill Prevention, Containment, and Countermeasure Plan, AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material, and AMM10 Restoration of Temporarily Affected Natural Communities. These AMMs include elements that avoid or minimize the risk of construction activity affecting habitat and species adjacent to work areas and storage sites. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.

Late Long-Term Timeframe

Alternative 1B as a whole would affect 2,578 acres of roosting habitat (Table 12-1B-61). Because the majority of affected acres would convert agricultural land to natural communities with higher potential foraging and roosting value, such as riparian, tidal and nontidal wetlands, and periodically inundated lands this analysis focuses only on losses of roosting habitat under CM1, CM2, CM4, and CM5.

Implementation of BDCP actions in the late long-term would result in an overall benefit to special-status bats within the study area through protection and restoration of approximately 142,200 acres of their foraging and roosting habitats (Objective L1.1). Achieving this objective is intended to protect the highest quality natural communities and covered species habitat in the Plan Area to optimize the ecological value of the reserve system for conserving covered species and native biodiversity. The target for total protected and restored acreage is based on the sum of all natural community acreage targets. Achieving this objective is intended to protect and restore natural communities, species-specific habitat elements, and species diversity on a landscape-scale. Achieving this objective is also intended to conserve representative natural and seminatural landscapes in order to maintain the ecological integrity of large habitat blocks, including desired ecosystem function, and biological diversity.
BDCP actions in the late long-term would restore and protect 5,750 acres of riparian roosting and foraging habitat (Objective VFRNC1.1 and Objective VFRNC1.2), and 136,450 acres of foraging habitat (Objective L1.1, Objective GNC1.2, Objective VPNC1.2, Objective L1.2, Objective L2.11, Objective L1.1, Objective ASWNC1.1, Objective VPNC1.1, Objective MWNC1.1, Objective CLNC1.1, Objective GGS3.1, and Objective GNC1.1,) in natural communities and developed lands. Restored foraging habitats would replace primarily cultivated lands. Restored habitats are expected to be of higher function because the production of flying insect prey species is expected to be greater in restored wetlands and uplands on which application of pesticides would be reduced relative to affected agricultural habitats.

Should any of the special-status bat species be detected roosting in the study area, construction of water conveyance facilities and restoration activities would have an adverse effect on roosting special-status bats. Noise and visual disturbances and the potential for injury or mortality of individuals associated within implementation of the restoration activities on active roosts would be minimized with implementation of Mitigation Measure BIO-166. Conservation components would sufficiently offset the adverse effects resulting from late long-term effects from CM1, CM2, CM4, and CM5.

NEPA Effects: In the near-term the losses of roosting habitat for special-status bats associated with implementing Alternative 1B are not expected to result in substantial adverse effects on special-status bats, either directly or through habitat modifications, and would not result in a substantial reduction in numbers or a restriction in the range of special-status bats because the BDCP has committed to protecting the acreage required to meet the typical mitigation ratios described above. In the late long-term, the losses of roosting habitat for special-status bats associated with Alternative 1B, in the absence of other conservation actions, would represent an adverse effect as a result of habitat modification and potential direct mortality of special-status species. However, with habitat protection and restoration associated with the conservation components, guided by landscape-scale goals and objectives and by AMM1–AMM6, and AMM10, and with implementation of Mitigation Measure BIO-166, the effects of Alternative 1B as a whole on special-status bats would not be adverse.

CEQA Conclusion:

Near-Term Timeframe

Because water conveyance facilities construction is being evaluated at the project level, the near-term BDCP strategy has been analyzed to determine whether it would provide sufficient habitat protection or restoration in an appropriate timeframe to ensure that the construction effects would be less than significant under CEQA. Because the majority of affected acres would convert agricultural land to natural communities with higher potential foraging and roosting value, such as riparian, tidal and nontidal wetlands, and periodically inundated lands this analysis focuses only on losses to roosting habitat for CM1, CM2, and CM4 in the near-term.

Alternative 1B would permanently or temporarily affect 1,487 acres of roosting habitat for special-status bats in the near-term as a result of implementing CM1 (796 acres roosting habitat), CM2 (256 acres roosting habitat), and CM4 (435 acres roosting habitat). Effects from CM5 would all occur in the late long-term. Most of the roosting habitat losses would occur in the valley/foothill riparian natural community.
Typical CEQA project-level mitigation ratios for those natural communities that would be affected for roosting habitat would be 1:1 for restoration and protection of the valley/foothill riparian natural community. Using these ratios would indicate that 1,487 acres of riparian habitat should be restored and 1,487 acres of riparian habitat should be protected.

Implementation of BDCP actions in the near-term would result in an overall benefit to special-status bats within the study area through protection and restoration of their foraging and roosting habitats (Objective L1.1). BDCP actions in the near-term would restore 800 acres of riparian roosting and foraging habitat (Objective VFRNC1.1) and 21,288 acres of foraging habitat in natural communities and developed lands (Objective L1.1, Objective GNC1.2, Objective VPNC1.2, Objective L1.2, and Objective L2.11). In addition, the BDCP would protect 750 acres of riparian roosting and foraging habitat (Objective VFRNC1.2) and 41,445 acres of foraging habitat (Objective L1.1, Objective ASWNC1.1, Objective VPNC1.1, Objective MWNC1.1, Objective CLNC1.1, Objective GNC1.1.). Restored foraging habitats would replace primarily cultivated lands. Restored habitats are expected to be of higher function because the production of flying insect prey species is expected to be greater in restored wetlands and uplands on which application of pesticides would be reduced relative to affected agricultural habitats. Conservation components in the near-term would sufficiently offset the adverse effects resulting from near-term effects from Alternative 1B.

In addition, activities associated with natural communities enhancement and protection and with ongoing facilities operations and maintenance could affect special-status bat use of surrounding habitat and could result in harassment, injury or mortality of bats. Mitigation Measure BIO-166, described below, requires preconstruction surveys to reduce these impacts to a less-than-significant level.

The permanent loss of roosting habitat from Alternative 1B would be mitigated through implementation of Mitigation Measure BIO-166, which would ensure there is no significant impact under CEQA on roosting special-status bats, either directly or through habitat modifications and no substantial reduction in numbers or a restriction in the range of special-status bats. The BDCP also contains commitments to implement AMM1–AMM6 and AMM10. These AMMs include elements that avoid or minimize the risk of construction activity affecting habitat and species adjacent to work areas and storage sites. The AMMs are described in detail in BDCP Appendix 3.C, Avoidance and Minimization Measures.

Late Long-Term Timeframe

Alternative 1B as a whole would affect 2,578 acres of roosting habitat (Table 12-1B-61). Because the majority of affected acres would convert agricultural land to natural communities with higher potential foraging and roosting value, such as riparian, tidal and nontidal wetlands, and periodically inundated lands this analysis focuses only on losses to roosting habitat for CM1, CM2, CM4, and CM5 in the late long-term.

Implementation of BDCP actions in the late long-term would result in an overall benefit to special-status bats within the study area through protection and restoration of approximately 142,200 acres of their foraging and roosting habitats (Objective L1.1). Achieving this objective is intended to protect the highest quality natural communities and covered species habitat in the Plan Area to optimize the ecological value of the reserve system for conserving covered species and native biodiversity. The target for total protected and restored acreage is based on the sum of all natural community acreage targets. Achieving this objective is intended to protect and restore natural communities, species-specific habitat elements, and species diversity on a landscape-scale,
Achieving this objective is also intended to conserve representative natural and seminatural landscapes in order to maintain the ecological integrity of large habitat blocks, including desired ecosystem function, and biological diversity.

BDCP actions in the late long-term would restore and protect 5,750 acres of riparian roosting and foraging habitat (Objective VFRNC1.1 and Objective VFRNC1.2), and 136,450 acres of foraging habitat (Objective L1.1, Objective GNC1.2, Objective VPNC1.2, Objective L1.2, Objective L2.11, Objective L1.1, Objective ASWNC1.1, Objective VPNC1.1, Objective MWNC1.1, Objective CLNC1.1, Objective GGS3.1, and Objective GNC1.1,) in natural communities and developed lands. Restored foraging habitats would replace primarily cultivated lands. Restored habitats are expected to be of higher function because the production of flying insect prey species is expected to be greater in restored wetlands and uplands on which application of pesticides would be reduced relative to affected agricultural habitats.

Should any of the special-status bat species roost in the study area, construction of water conveyance facilities and restoration activities would have an adverse effect on roosting special-status bats. Noise and visual disturbances and the potential injury or mortality of individuals as a result of implementation of the Alternative 1B activities would be minimized with implementation of Mitigation Measure BIO-166, Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures. Conservation components would sufficiently offset the adverse effects resulting from late long-term effects from CM1, CM2, CM4, and CM5. The permanent loss of roosting habitat resulting from Alternative 1B would be mitigated through implementation of Mitigation Measure BIO-166, which would ensure there is no significant impact under CEQA on roosting special-status bats, either directly or through habitat modifications, and no substantial reduction in numbers or a restriction in the range of special-status bats. Therefore, Alternative 1B would not result in a significant impact on special-status bats under CEQA.

**Mitigation Measure BIO-166: Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures**

The following measure was designed to avoid and minimize adverse effects on special-status bats. However, baseline data are not available or are limited on how bats use the study area, and on individual numbers of bats and how they vary seasonally. Therefore, it is difficult to determine if there would be a substantial reduction in species numbers. Bat species with potential to occur in the study area employ varied roost strategies, from solitary roosting in foliage of trees to colonial roosting in trees and artificial structures, such as buildings and bridges. Daily and seasonal variations in habitat use are common. To obtain the highest likelihood of detection, preconstruction bat surveys will be conducted by DWR and will include these components.

- Identification of potential roosting habitat within project area.
- Daytime search for bats and bat sign in and around identified habitat.
- Evening emergence surveys at potential day-roost sites, using night-vision goggles and/or active full-spectrum acoustic monitoring where species identification is sought.
- Passive full-spectrum acoustic monitoring and analysis to detect bat use of the area from dusk to dawn over multiple nights.
• Additional on-site night surveys as needed following passive acoustic detection of special status bats to determine nature of bat use of the structure in question (e.g., use of structure as night roost between foraging bouts).

• Qualified biologists will have knowledge of the natural history of the species that could occur in the study area and experience using full-spectrum acoustic equipment. During surveys, biologists will avoid unnecessary disturbance of occupied roosts.

Preconstruction Bridges and Other Structure Surveys

Before work begins on the bridge/structure, qualified biologists will conduct a daytime search for bat sign and evening emergence surveys to determine if the bridge/structure is being used as a roost. Biologists conducting daytime surveys would listen for audible bat calls and would use naked eye, binoculars, and a high-powered spotlight to inspect expansion joints, weep holes, and other bridge features that could house bats. Bridge surfaces and the ground around the bridge/structure would be surveyed for bat sign, such as guano, staining, and prey remains.

Evening emergence surveys will consist of at least one biologist stationed on each side of the bridge/structure watching for emerging bats from a half hour before sunset to 1–2 hours after sunset for a minimum of two nights within the season that construction would be taking place. Night-vision goggles and/or full-spectrum acoustic detectors shall be used during emergence surveys to assist in species identification. All emergence surveys would be conducted during favorable weather conditions (calm nights with temperatures conducive to bat activity and no precipitation predicted).

Additionally, passive monitoring with full-spectrum bat detectors will be used to assist in determining species present. A minimum of four nights of acoustic monitoring surveys will be conducted within the season that the construction would be taking place. If site security allows, detectors should be set to record bat calls for the duration of each night. To the extent possible, all monitoring will be conducted during favorable weather conditions (calm nights with temperatures conducive to bat activity and no precipitation predicted). The biologists will analyze the bat call data using appropriate software and prepare a report with the results of the surveys. If acoustic data suggest that bats may be using the bridge/structure as a night roost, biologists will conduct a night survey from 1–2 hours past sunset up to 6 hours past sunset to determine if the bridge is serving as a colonial night roost.

If suitable roost structures would be removed, additional surveys may be required to determine how the structure is used by bats, whether it is as a night roost, maternity roosts, migration stopover, or for hibernation.

Preconstruction Tree Surveys

If tree removal or trimming is necessary, qualified biologists will examine trees to be removed or trimmed for suitable bat roosting habitat. High-value habitat features (large tree cavities, basal hollows, loose or peeling bark, larger snags, palm trees with intact thatch, etc.) will be identified and the area around these features searched for bats and bat sign (guano, culled insect parts, staining, etc.). Riparian woodland, orchards, and stands of mature broadleaf trees should be considered potential habitat for solitary foliage roosting bat species.

If bat sign is detected, biologists will conduct evening visual emergence survey of the source habitat feature, from a half hour before sunset to 1–2 hours after sunset for a minimum of two
nights within the season that construction would be taking place. Methodology should follow 
that described above for the bridge emergence survey.

Additionally, if suitable tree roosting habitat is present, acoustic monitoring with a bat detector 
will be used to assist in determining species present. These surveys would be conducted in 
coordination with the acoustic monitoring conducted for the bridge/structure.

**Protective Measures for Bats using Bridges/Structures and Trees**

Avoidance and minimization measures may be necessary if it is determined that bats are using 
the bridge/structure or trees as roost sites and/or sensitive bats species are detected during 
acoustic monitoring. Appropriate measures will be determined in coordination with CDFW and 
may include measures listed below.

- Disturbance of the bridge will be avoided between April 15 and September 15 (the 
  maternity period) to avoid impacts on reproductively active females and dependent young.
- Installation of exclusion devices from March 1 through April 14 or September 15 through 
  October 30 to preclude bats from occupying the bridge during construction. Exclusionary 
  devices will only be installed by or under the supervision of an experienced bat biologist.
- Tree removal will be avoided between April 15 and September 15 (the maternity period) to 
  avoid impacts on pregnant females and active maternity roosts (whether colonial or 
  solitary).
- All tree removal would be conducted between September 15 and October 30, which 
  corresponds to a time period when bats would not likely have entered winter hibernation 
  and would not be caring for flightless young. If weather conditions remain conducive to 
  regular bat activity beyond October 30th, later tree removal may be considered in 
  consultation with CDFW.
- Trees would be removed in pieces, rather than felling the entire tree.
- If a maternity roost is located, whether solitary or colonial, that roost will remain 
  undisturbed with a buffer as determined in consultation with CDFW until September 15 or 
  until a qualified biologist has determined the roost is no longer active.
- If a non-maternity roost is found, that roost will be avoided and an appropriate buffer 
  established in consultation with CDFW. Every effort should be made to avoid the roost, as 
  methods to evict bats from trees are largely untested. However, if the roost cannot be 
  avoided, eviction would be attempted and procedures designed in consultation with CDFW 
  to reduce the likelihood of mortality of evicted bats. In all cases:
  - Eviction will not occur before September 15th and will match the timeframe for tree 
    removal approved by CDFW.
  - Qualified biologists will carry out or oversee the eviction tasks monitor the tree 
    trimming/removal.
  - Eviction will take place late in the day or in the evening to reduce the likelihood of 
    evicted bats falling prey to diurnal predators.
  - Eviction will take place during weather and temperature conditions conducive to bat 
    activity.
Special-status bat roosts will not be disturbed.

Eviction procedures may include but are not limited to:

- Pre-eviction surveys to obtain data to inform the eviction approach and subsequent mitigation requirements. Relevant data may include the species, sex, reproductive status and/or number of bats using the roost, and roost conditions themselves such as temperature and dimensions. Surveys may include visual emergence, night vision, acoustic, and/or capture.
- Structural changes may be made to the roost, performed without harming bats, such that the conditions in the roost are undesirable to roosting bats and the bats leave on their own (e.g., open additional portals so that temperature, wind, light and precipitation regime in the roost change).
- Noninjurious harassment at the roost site to encourage bats to leave on their own, such as ultrasound deterrents or other sensory irritants.

Prior to removal/trimming, after other eviction efforts have been attempted, any confirmed roost tree would be shaken, repeatedly struck with a heavy implement such as an axe and several minutes should pass before felling trees or trimming limbs to allow bats time to arouse and leave the tree. The biologists should search downed vegetation for dead and injured bats. The presence of dead or injured bats would be reported to CDFW.

Compensatory mitigation for the loss of roosting habitat will also be determined through consultation with CDFW and may include the construction and installation of suitable replacement habitat onsite. Depending on the species and type of roost lost, various roost replacement habitats have met with some success (e.g., bat houses, "bat bark," planting cottonwood trees, leaving palm thatch in place rather than trimming). The creation of natural habitat onsite is generally preferable to artificial.

Artificial roosts are often unsuccessful, and care must be taken to determine as closely as possible the conditions in the natural roost to be replaced. Even with such care, artificial habitat may fail. Several artificial roosts have been highly successful in replacing bridge roost habitat when incorporated into new bridge designs. “Bat bark” has been successfully used by Arizona Department of Game and Fish to create artificial crevice-roosting bat habitat mounted on pine trees (Mering and Chambers 2012: 765). Bat houses have at best an inconsistent track record but information is mounting on how to create successful houses. There is no single protocol or recipe for bat-house success. Careful study of the roost requirements of the species in question; the particular conditions at the lost roost site including temperature, orientation of the openings, airflow, internal dimensions and structures (cavity vs. crevice, etc.) should increase the chances of designing a successful replacement.

Restoring riparian woodland with plantings shows signs of success in Colorado. Western red bat activity has been positively correlated with increased vegetation and tree growth, canopy complexity and restoration acreage at cottonwood-willow restoration sites along the Lower Colorado River (Broderick 2012: 39). These complex woodland areas would ultimately provide a wider range of bat species with preferred roost types, including both foliage-roosting and crevice-/cavity-roosting bats.
Impact BIO-167: Indirect Effects of Plan Implementation on Special-Status Bats

Construction activities associated with water conveyance facilities, conservation components and ongoing habitat enhancement, as well as operations and maintenance of above-ground water conveyance facilities, including the transmission facilities, could result in ongoing periodic postconstruction disturbances and noise with localized effects on special-status bats and their roosting habitat over the term of the BDCP.

Water conveyance facilities operations and maintenance activities would include vegetation and weed control, ground squirrel control, canal maintenance, infrastructure and road maintenance, levee maintenance, and maintenance and upgrade of electrical systems. While maintenance activities are not expected to remove special-status bat habitat, operation of equipment could disturb small areas of vegetation around maintained structures and could result in disturbances to roosting bats, if present. Mitigation Measure BIO-166, Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures, is available to address these adverse effects.

Increased exposure to methylmercury associated with tidal natural communities restoration would potentially indirectly affect special-status bat species. CM12 Methylmercury Management describes the process by which tidal natural communities restoration may increase methyl mercury levels in wetlands in the study area. Mercury has been found in high concentrations in some bat species, such as the Indiana bat. Many bat species forage heavily on aquatic insects, which might result in rapid bioaccumulation (Evers et al. 2012). Measures described in CM12 Methylmercury Management are expected to reduce the effects of methylmercury on special-status bat species resulting from BDCP tidal natural communities restoration.

NEPA Effects: Implementation of the Mitigation Measure BIO-166 for special-status bats would avoid the potential for substantial adverse effects on roosting special-status bats, either indirectly or through habitat modifications. This mitigation measure would also avoid and minimize effects that could substantially reduce the number of special-status bats, or restrict species’ range. Therefore, the indirect effects of Alternative 1B would not have an adverse effect on special-status bats.

CEQA Conclusion: Indirect effects from conservation components operations and maintenance as well as construction-related noise and visual disturbances could have a significant impact on special-status bat species, either indirectly or through habitat modifications. Mitigation Measure BIO-166, Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures, would reduce this impact to a less-than-significant level and ensure Alternative 1B would not result in a substantial reduction in numbers or a restriction in the range of species.

Mitigation Measure BIO-166: Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures

See Mitigation Measure BIO-166 under Impact BIO-166.

Impact BIO-168: Periodic Effects of Inundation of Special-Status Bat Habitat as a Result of Implementation of Conservation Components

Flooding of the Yolo Bypass from CM2 Yolo Bypass Fisheries Enhancement would periodically affect 324 acres of roosting habitat and 21,265 acres of foraging habitat for special-status bats in the study area (Table 12-1B-61).
**CM5 Seasonally Inundated Floodplain Restoration** would periodically inundate up to 411 acres of roosting habitat and 10,137 acres of foraging habitat for special-status bats (Table 12-1B-61). Potential roosting trees are likely to be retained within seasonally flooded areas, although high velocity flooding could uproot some trees. Seasonal flooding would not adversely affect foraging habitat for the species. The overall effect of seasonal inundation in existing riparian natural communities may instead be beneficial. Historically, flooding was the main natural disturbance regulating ecological processes in riparian areas, and flooding promotes the germination and establishment of many native riparian plants. In the late long-term, seasonal inundation in areas currently occupied by riparian vegetation may contribute to the establishment of high-value habitat for special-status bats that use riparian habitats.

**NEPA Effects:** Periodic effects on roosting and foraging habitat for special-status bats associated with implementing Alternative 1B are not expected to result in substantial adverse effects on special-status bats, either directly or through habitat modifications and would not result in a substantial reduction in numbers or a restriction in the range of special-status bats. Mitigation Measure BIO-166, *Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures*, is available to address any effects of periodic inundation on special-status bats and roosting habitat. Therefore, Alternative 1B would not adversely affect the species.

**CEQA Conclusion:** Periodic inundation under CM2 and floodplain restoration under CM5 would periodically affect foraging and roosting habitat for special-status bats in the study area. Any impact of periodic inundation on special-status bats would be mitigated through implementation of Mitigation Measure BIO-166, which would ensure there is no significant impact on roosting special-status bats, either directly or through habitat modifications and no substantial reduction in numbers or a restriction in the range of special-status bats.

**Mitigation Measure BIO-166: Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures**

See Mitigation Measure BIO-166 under Impact BIO-166.

**Plant Species**

**Vernal Pool Plants**

Five covered plant species and 12 noncovered special-status plant species occur in vernal pools in the study area (Tables 12-2, 12-3, summarized in Table 12-1B-62). The vernal pool habitat model used for the impact analysis was based on vegetation types and associations from various data sets which were used to create maps showing the distribution of vernal pool habitat in the study area according to three habitat types in which the species are known to occur, including vernal pool complex and degraded vernal pool complex, and alkali seasonal wetland habitat. Vernal pool complex habitat consists of vernal pools and uplands that display characteristic vernal pool and swale visual signatures that have not been significantly impacted by agricultural or development practices. Degraded vernal pool complex habitat consists of habitat that ranges from areas with vernal pool and swale visual signatures that display clear evidence of significant disturbance due to plowing, discing, or leveling to areas with clearly artificial basins such as shallow agricultural ditches, depressions in fallow fields, and areas of compacted soils in pastures. Because wetlands in the degraded vernal pool complex are inundated during the wet season and may have historically been located in or near areas with natural vernal pool complex, they may support individuals or
small populations of species that are found in vernal pools and swales. However, they do not possess
the full complement of ecosystem and community characteristics of natural vernal pools, swales and
their associated uplands and they are generally ephemeral features that are eliminated during the
course of normal agricultural practices. A small amount of alkali seasonal wetland habitat was
included in the model because alkaline vernal pools are also present in some areas mapped as alkali
seasonal wetland.

Because each of the vernal pool species addressed in this EIR/EIS have specific microhabitat
affinities, and because vernal pool habitat within the study area is highly heterogeneous with
respect to habitat parameters such as soil type and pool depth, the vernal pool habitat model greatly
overestimates the extent of habitat in the study area occupied by each species. However, the vernal
pool habitat model is likely to encompass all or most of the potential area within which special-
status vernal pool plant species would occur. Therefore, it is not likely to underestimate the extent
of occupied habitat or to underestimate the effects of Alternative 1B.

Full implementation of Alternative 1B would include the following conservation actions over the
term of the BDCP to benefit covered vernal pool plants (BDCP Chapter 3, Section 3.3, Effects on
Covered Wildlife and Plant Species).

- Protect two currently unprotected occurrences of alkali milk-vetch in the Altamont Hills or
  Jepson Prairie core recovery areas (Objective VPP1.1, associated with CM3).

- Maintain no net loss of Heckard’s peppergrass in Conservation Zones 1, 8, or 11 within
  restoration sites or within the area of affected tidal range of restoration projects (Objective
  VPP1.2, associated with CM3 and CM9).

The construction and restoration activities covered under Alternative 1B could have impacts on
special-status vernal pool plants. Modeled vernal pool habitat is within the proposed footprint for
the Alternative 1B water conveyance facilities and within the hypothetical footprints for restoration
activities, although no known occurrences of the 17 covered and noncovered vernal pool plant
species is within the proposed footprint for the Alternative 1B water conveyance facilities or the
footprint for restoration activities. Table 12-1B-62 summarizes the acreage of modeled vernal pool
habitat in the study area, the number of occurrences of each special-status vernal pool plant in the
study area, and potential effects.

**Impact BIO-169: Effects on Habitat and Populations of Vernal Pool Plants**

Alternative 1B could affect habitat for special-status vernal pool plants. The individual effects of each relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- **CM1 Water Facilities and Operations**: Four acres of modeled habitat would be removed by construction of the water conveyance facilities. However, no known occurrences of the 17 special-status vernal pool plants are within the proposed footprint for the Alternative 1B water conveyance facilities. Because the proposed footprint for the Alternative 1B water conveyance...
facilities affects very little modeled habitat, effects on undiscovered occurrences of special-status vernal pool plant species are highly unlikely.

- **CM2 Yolo Bypass Fisheries Enhancement**: No modeled vernal pool habitat and no known occurrences of special-status vernal pool plants are within the hypothetical footprint for construction or operation of the Yolo Bypass fisheries enhancements.

- **CM3 Natural Communities Protection and Restoration**: The BDCP proposes to benefit covered vernal pool plants by protecting 600 acres of vernal pool complex in CZ 1, CZ 8, and CZ 11 (Objective VPNC1.1). The protected vernal pool habitat would be managed and enhanced to sustain populations of native vernal pool species. These benefits also would accrue to any noncovered vernal pool plants occurring in the protected vernal pool complex.

- **CM4 Tidal Natural Communities Restoration**: Tidal habitat restoration would result in the inundation of 373 acres of vernal pool complex and would, therefore, potentially affect special-status vernal pool plants. However, most of this habitat (373 acres) consists of degraded vernal pool habitat that is unlikely to contain special-status plants. In addition, 257.8 acres of critical habitat for Contra Costa goldfields could be affected. No known occurrences of covered and noncovered vernal pool plants would be affected by tidal restoration.

- **CM5 Seasonally Inundated Floodplain Restoration**: No vernal pool habitat or occurrences of special-status vernal pool plants are present within areas proposed for floodplain restoration. Therefore, floodplain restoration and construction of new floodplain levees would have no impacts on covered and noncovered vernal pool plants.

- **CM6 Channel Margin Enhancement**: No vernal pool habitat or occurrences of special-status vernal pool plants are present within areas proposed for channel margin habitat enhancement. Therefore, channel margin habitat enhancement would have no impacts on covered and noncovered vernal pool plants.

- **CM7 Riparian Natural Community Restoration**: No vernal pool habitat or occurrences of special-status vernal pool plants are present within areas proposed for riparian habitat enhancement. Therefore, riparian habitat enhancement would have no impacts on covered and noncovered vernal pool plants.

- **CM8 Grassland Natural Community Restoration**: Although the vernal pool complex habitat includes grassland matrix within which the vernal pools occur, grassland restoration activities would take place in non-grasslands (ruderal habitat, cultivated land) or degraded grasslands that are not included within vernal pool complex habitat. Therefore, grassland communities restoration would have no impacts on covered and noncovered vernal pool plants.

- **CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration**: If, through unforeseen circumstances, BDCP activities result in the net loss of vernal pool habitat, CM9 would be implemented to compensate for that loss. Because vernal pool complex restoration would focus on habitat that had been cleared and leveled but maintained an intact duripan or claypan, the likelihood of affecting any special-status vernal pool plants would be low. However, vernal pool restoration potentially could adversely affect remnant populations of special-status vernal pool plants or potentially affect vernal pool habitat adjacent to the restoration areas.

- **CM10 Nontidal Marsh Restoration**: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid vernal pool habitat and would have no impacts on covered and noncovered vernal pool plants.
Alternative 1B
Terrestrial Biological Resources

- **CM22 Avoidance and Minimization Measures**: Effects on covered vernal pool plants potentially resulting from implementation of CM4 would be avoided or minimized through AMM11 Covered Plant Species, AMM2 Construction Best Management Practices and Monitoring, AMM12 Vernal pool Crustaceans, and AMM12 Vernal Pool Crustaceans. AMM11 prohibits ground disturbance or hydrologic disturbance within 250 feet of existing vernal pools. In addition, AMM11 specifies that individual projects be designed to avoid critical habitat for listed plant and wildlife vernal pool species. AMM12 limits the direct removal of vernal pool crustacean habitat to no more than 10 wetted acres and the indirect effect to no more than 20 wetted acres through the life of the Plan. AMM12 also requires that that tidal natural communities restoration or other ground-disturbing covered activities in Conservation Zones 1 and 11 will not result in the adverse modification of primary constituent elements of critical habitat for vernal pool fairy shrimp, conservancy fairy shrimp, and vernal pool tadpole shrimp. These protections would also apply to critical habitat for Contra Costa goldfields, where it overlaps with critical habitat for these vernal pool crustaceans. AMM37 requires that new recreation trails avoid populations of covered vernal pool plants.

In addition, the BDCP includes species-specific goals to benefit covered vernal pool plants. This includes protecting two occurrences of alkali milkvetch (Objective VPP1.1) and requiring no net loss of Heckard’s peppergrass (Objective VPP1.2).

In summary, no adverse effects on covered special-status vernal pool plants would be expected from implementing Alternative 1B. No known occurrences of special-status vernal pool plants would be affected. Beneficial effects on special-status vernal pool plants could occur by protecting 600 acres of vernal pool complex in CZ 1, CZ 8, and CZ 11 and by protecting occurrences of alkali milk-vetch.

The GIS analysis estimated that up to 375 acres of vernal pool complex could be adversely affected by covered activities under Alternative 1B. However, the actual effect on habitat for special-status vernal pool plants is expected to be much less than the estimated impact because the BDCP limits the total loss of wetted vernal pool habitat resulting from specific projects to 10 acres (approximately 67 acres of vernal pool complex) over the permit term (AMM12). At the proposed restoration ratios of 1:1 (prior to impact) and 1.5:1 (concurrent with impact), between 67 and 100.5 acres of vernal pool complex restoration would be required to compensate for the loss of modeled habitat for special-status vernal pool plants (Objective VPNC1.2, associated with CM9). This would be consistent with typical NEPA and CEQA project-level mitigation ratios for vernal pool impacts. The limitation on the loss of wetted vernal pool habitat would constrain the implementation of tidal restoration projects that are adjacent to vernal pool complex, which could affect the feasibility of restoring 65,000 acres of tidal habitat (Objective TPANC1.1, associated with CM4).

**NEPA Effects**: The loss of modeled habitat for vernal pool plant species would be minimized by AMM12 and offset through CM9. Therefore, Alternative 1B would not result in adverse effects on covered and noncovered vernal pool plant species.

**CEQA Conclusion**: Because loss of modeled habitat for covered vernal pool plants would be offset through restoration, and because impacts on occurrences of covered vernal pool plants would be avoided, the impacts of implementing Alternative 1B on covered and noncovered special-status vernal pool plants in the study area would be less than significant. No mitigation is required.
**Alkali Seasonal Wetland Plants**

Five covered species and three noncovered plants occur in alkali seasonal wetlands in the study area (Tables 12-2, 12-3, summarized in Table 12-1B-63). Alkali seasonal wetland habitat was modeled separately for four covered plant species occurring in seasonal alkali wetlands.

The San Joaquin spearscale habitat model approximated the distribution of suitable San Joaquin spearscale habitat in the study area according to the species' preferred habitat types, intersected with soil series and slope position. Historical and current records of San Joaquin spearscale in the study area indicate that its current distribution is limited to alkaline soil areas with shallow basin or swale microtopography along the western border. The vegetation cover of the alkaline soils is typically a combination of alkaline soil-adapted species and annual grasses, including annual ryegrass and Mediterranean barley. Habitat types used for the model included alkali seasonal wetlands, vernal pool complex, and grasslands. Soil series used in the model consisted of either clays or clay loams with alkaline horizons. San Joaquin spearscale typically occurs in swales or in level terrain but occasionally occurs on the lower slopes adjacent to streams or swales or where seeps are present. Because some of the soil series with which San Joaquin spearscale is associated can occur on hillsides, slope was used to limit the extent of the model to the toe of the slope where these soils occur by excluding areas with slope greater than 1%. Land uses that are incompatible with the species' habitat requirements, such as modeled habitat polygons falling on leveled or developed lands, were removed from the model.

Modeled habitat for brittlescale was mapped as hydrologic features such as stream corridors and playa pools located on alluvium associated with the Montezuma Block along the western boundary of the study area or on alluvium associated with tertiary formations located along the southwest boundary of the study area. Stream corridors (intermittent and perennial) that intersected these geologic units were selected and truncated at the point at which they encountered the upper elevation of intertidal marsh. The corridors were buffered 50 feet (15.2 meters) on either side of their centerlines to capture the estimated maximum extent of alluvium deposits in proximity to the streams. Mapped habitat that was occupied by urban or intensive agricultural uses was removed from the model.

The habitat model for heartscale was based on the species distribution in the study area (Solano and Yolo Counties) and on the soil types and plant communities within which it occurs. Potential habitat was determined by intersecting the GIS coverage for three parameters: 1) Yolo and Solano County boundaries; 2) Solano, Pescadero, and Willows soils; and 3) grassland, alkali seasonal wetland, and vernal pool complex natural communities. The model excluded areas that have been developed or cultivated, i.e., where the topography, soils, and hydrology have been substantially altered.

Delta button-celery habitat was modeled as alkali seasonal wetland complex, vernal pool complex, other natural seasonal wetland, and grassland occurring on Brentwood, Grangerville, Marcuse, Solano, and Vernalis soil map units within the San Joaquin Basin (i.e., south of the mainstem San Joaquin River). For this species, land cover north of the Discovery Bay area where intensive agriculture was classified as annual grassland were manually deleted from the area of predicted habitat. Additionally, other areas of potential habitat that have been developed were also manually deleted.

Full implementation of Alternative 1B would include the following conservation actions over the term of the BDCP to benefit covered alkali seasonal wetland plants (BDCP Chapter 3, Section 3.3, *Effects on Covered Wildlife and Plant Species*).
• Of the 150 acres of alkali seasonal wetland complex protected under Objective ASWNC1.1, 600 acres of vernal pool complex protected under Objective VPNC1.1, and 8,000 acres of grassland natural community protected under Objective GNC1.1, protect 75 acres of suitable brittlescale habitat and 75 acres of suitable heartscale habitat in Conservation Zones 1, 8, or 11 (Objective BRIT/HART/SJSC1.1, associated with CM3).

• Protect two currently unprotected occurrences of San Joaquin spearscale in Conservation Zones 1, 8, or 11 (Objective BRIT/HART/SJSC1.2, associated with CM3).

Alternative 1B would have adverse effects on modeled habitat for San Joaquin spearscale, brittlescale, heartscale, and Delta button-celery. It would also have adverse effects on occurrences of heartscale, Heckard's peppergrass, and crownscale. Table 12-1B-63 summarizes the acreage of modeled alkali seasonal wetland habitat in the study area and the number of occurrences of each special-status alkali seasonal wetland plant in the study area.

<sup>a</sup> A portion of this acreage consists of riparian habitat.

<sup>b</sup> A second occurrence in study area is in riparian habitat.

<sup>c</sup> Four additional occurrences of Heckard’s peppergrass are associated with vernal pools.
Impact BIO-170: Effects on Habitat and Populations of Alkali Seasonal Wetland Plants

Modeled habitat for Delta button-celery would be adversely affected by construction of the Alternative 1B water conveyance facilities. One population of crownscale also would be adversely affected by construction of the water conveyance facilities. Modeled habitat for brittlescale and heartscale could be adversely affected by tidal habitat restoration. One occurrence each of heartscale and Heckard’s peppergrass could be affected by tidal habitat restoration. No adverse effects on palmate-bracted bird’s-beak or recurved larkspur would be expected.

The individual effects of each relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- **CM1 Water Facilities and Operations:** Under Alternative 1B, construction of the Byron Tract Forebay would permanently remove 69 acres of modeled habitat for San Joaquin spearscale and 21 acres of modeled habitat for Delta button-celery. This could be an adverse effect, depending on whether the affected modeled habitat is actually occupied by the species. Modeled habitat is assumed to encompass all potential habitat for a species and may therefore overestimate the area actually occupied. Known occurrences of San Joaquin spearscale near the forebay do not appear to be affected by facilities construction. Delta button-celery is not known to occur in CZ 8; the nearest known occurrence, in CZ 9, would not be affected.

Construction of the water conveyance facilities would permanently remove 0.2 acre of habitat occupied by crownscale at the Byron Tract Forebay. Part of the occurrence would be removed, but most of the occurrence would not be directly affected. However, a reduction of the population size, both in area and number of individuals present, would be an adverse impact.

Construction of the water conveyance facilities would not affect brittlescale, heartscale, Heckard’s peppergrass, palmate-bracted bird’s-beak, or recurved larkspur.

- **CM2 Yolo Bypass Fisheries Enhancement:** Construction of the Yolo Bypass fisheries enhancements would permanently remove 56 acres of modeled habitat for San Joaquin spearscale. No known occurrences of San Joaquin spearscale would be affected. No modeled habitat and no known occurrences of the seven other alkali seasonal wetland plants are within the hypothetical footprint for construction or operation of the Yolo Bypass fisheries enhancements.

- **CM3 Natural Communities Protection and Restoration:** The BDCP proposes to benefit alkali seasonal wetland plants by protecting 150 acres of alkali seasonal wetland in Conservation Zones 1, 8, and/or 11. The protected alkali seasonal wetland habitat would be managed and enhanced to sustain populations of native plant species.

- **CM4 Tidal Natural Communities Restoration:** Tidal habitat restoration is expected to convert alkali seasonal wetlands on the margins of tidal wetlands to freshwater or brackish tidal marsh. Tidal habitat restoration would convert 622 acres of modeled habitat for San Joaquin spearscale to tidal marsh. Tidal habitat restoration would permanently remove 4 acres of modeled habitat for brittlescale in CZ 1 near Lindsey Slough and in CZ 11 near Nurse Slough; however, the BDCP would allow up to 50 acres of modeled habitat to be converted to tidal wetlands. Tidal habitat restoration would remove 306 acres of modeled habitat for heartscale in CZ 1 in the vicinity of Jepson Prairie and in CZ 11 adjacent to Suisun Marsh. The extent to which the modeled habitat is actually occupied by these species is not known; modeled habitat is assumed to encompass all potential habitat for a species and may therefore overestimate the area actually occupied. Tidal
habitat restoration could adversely affect one occurrence of Heckard's peppergrass at Hass Slough and one occurrence of San Joaquin spearscale at Main Prairie, both in CZ 1. These occurrences are based on historic records, and whether the populations still exist is not known. In each case, the loss of modeled habitat and occurrences for covered species would be adverse effects. Delta button celery, crowscale, palmate-bracted bird's-beak, and recurved larkspur would not be affected by tidal habitat restoration.

- **CM5 Seasonally Inundated Floodplain Restoration**: Floodplain restoration levee construction would result in the removal of 2 acres of modeled habitat for San Joaquin spearscale. No known occurrences of San Joaquin spearscale would be affected. No other alkali seasonal wetland habitat or occurrences of special-status alkali seasonal wetland plants are present within areas proposed for floodplain restoration. Therefore, floodplain restoration and construction of new floodplain levees would have no impacts on covered and noncovered alkali seasonal wetland plants.

- **CM6 Channel Margin Enhancement**: No alkali seasonal wetland habitat or occurrences of special-status alkali seasonal wetland plants are present within areas proposed for channel margin habitat enhancement. Therefore, channel margin habitat enhancement would have no impacts on covered and noncovered alkali seasonal wetland plants.

- **CM7 Riparian Natural Community Restoration**: No alkali seasonal wetland habitat or occurrences of special-status alkali seasonal wetland plants are present within areas proposed for riparian habitat enhancement. Therefore, riparian habitat enhancement would have no impacts on covered and noncovered alkali seasonal wetland plants.

- **CM8 Grassland Natural Community Restoration**: Although the alkali seasonal wetland habitat includes the grassland matrix within which the wetlands occur, grassland restoration activities would take place in non-grasslands (ruderal habitat, cultivated land) or degraded grasslands that are not included within alkali seasonal wetland habitat. Therefore, grassland communities restoration would have no impacts on covered and noncovered alkali seasonal wetland plants.

- **CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration**: Although some vernal pools are alkaline, alkali seasonal wetlands in the study area consist of alkali grassland, alkali meadow, or iodine bush scrub. Therefore, vernal pool restoration would avoid alkali seasonal wetland habitat and would have no impacts on covered and noncovered alkali seasonal wetland plants. In addition, the BDCP would compensate for the loss of alkali seasonal wetlands from other CMs by restoring or creating 72 acres of alkali seasonal wetlands in Conservation Zones 1, 8, or 11 to achieve no net loss of this habitat.

- **CM10 Nontidal Marsh Restoration**: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid alkali seasonal wetland habitat and would have no impacts on covered and noncovered alkali seasonal wetland plants.

- **CM22 Avoidance and Minimization Measures**: Effects on special-status alkali seasonal wetland plants potentially resulting from implementation of CM1 and CM4 would be avoided or minimized though **AMM1 Covered Plant Species, AMM2 Construction Best Management Practices and Monitoring**, and **AMM37 Recreation**. Under AMM11, surveys for covered plant species would be performed during the planning phase of projects, and any impacts on populations of covered species would be avoided through project design or subsequently minimized though AMM2. In addition, AMM11 prohibits ground disturbance or hydrologic disturbance within 250 feet of
existing vernal pools, which would protect those species with modeled habitat that includes
vernal pool complex. Occurrences of covered species in vernal pools near tidal wetlands would
not be affected by tidal habitat restoration where critical habitat for vernal pool species is
present and would be avoided under AMM11. AMM37 requires that new recreation trails avoid
populations of covered alkali seasonal wetland plants.

In summary, only one known occurrence of a special-status alkali seasonal wetland species
(crownscale) would be affected under Alternative 1B, although one historic occurrence of Heckard’s
peppergrass and one historic occurrence of San Joaquin spearscale could also be affected by tidal
restoration activities, if those occurrences still exist. AMM11 would be implemented to avoid an
adverse effect on Heckard’s peppergrass and San Joaquin spearscale occurrences.

The primary effect of the Alternative 1B on special-status alkali seasonal wetland plants would be
the loss of potential (i.e., modeled) habitat for San Joaquin spearscale, brittlescale, heartscale, and
Delta button-celery. Approximately 72 acres of this habitat loss would be alkali seasonal wetlands.
The actual effect on modeled habitat for alkali seasonal wetland plants is expected to be somewhat
less than the estimated impact because some of this habitat is composed of vernal pool complex, and
the BDCP limits the total loss of wetted vernal pool habitat to 10 acres (approximately 67 acres of
vernal pool complex) over the permit term (AMM12). Loss of modeled habitat would be
compensated for by restoring or creating vernal pool complex, alkali seasonal wetlands, and
grasslands, in proportion to the amount of each habitat removed. At the proposed restoration ratios
of 1:1 (prior to impact) and 1.5:1 (concurrent with impact), between 67 and 100.5 acres of vernal
pool complex restoration would be required to compensate for the loss of modeled habitat
composed of vernal pool complex (Objective VPNC1.2, associated with CM9). Approximately 72
acres of alkali seasonal wetlands would be restored (Objective ASWC1.2, associated with CM9). Loss
of modeled habitat composed of grasslands would be compensated for by restoring grassland
habitat on a 1:1 basis (Objective GNC1.1, associated with CM8). These compensation levels would be
consistent with typical NEPA and CEQA project-level mitigation ratios for impacts on vernal pools,
alkali seasonal wetlands, and grasslands.

The BDCP would have a small beneficial effect on special-status alkali seasonal wetland plants by
protecting 150 acres of alkali seasonal wetland habitat. The BDCP also includes the species-specific
goal that 75 acres would be modeled habitat for brittlescale and heartscale (Objective
BRIT/HART/JSC1.1) and another goal that would protect 2 occurrences of San Joaquin spearscale
(Objective BRIT/HART/JSC1.1). The benefits of habitat protection and management also would
accrue to any noncovered alkali seasonal wetland plants occurring in the protected habitat.

**NEPA Effects:** Under Alternative 1B, loss of modeled habitat for alkali seasonal wetland plant
species would be offset through restoration of grassland, vernal pool, and alkali seasonal wetland
habitat (CM8, CM9), and impacts on one occurrence of San Joaquin spearscale and one occurrence of
Heckard’s peppergrass would be avoided through AMM11. With avoidance and habitat restoration,
these effects would not be adverse. The loss of one occurrence of crownscale, a noncovered species,
would result in a reduction in the range and numbers of this species and would be an adverse effect.
Adverse effects on crownscale could be avoided or offset through implementation of Mitigation
Measure BIO-170, Avoid, Minimize, or Compensate for Impacts on Noncovered Special-Status Plant
Species.

**CEQA Conclusion:** Because loss of modeled habitat for alkali seasonal wetland plant species would
be offset through restoration, and because impacts on occurrences of covered alkali seasonal
Terrestrial Biological Resources

wetland plants would be avoided, impacts on alkali seasonal wetlands as a result of implementing Alternative 1B would not result in substantially reducing the number or restricting the range of five covered and two noncovered plant species. However, conservation measures that benefit or protect covered species do not apply to noncovered species, and portions of the crownscale population at Byron Tract Forebay would be lost, which would be a significant impact. Mitigation Measure BIO-170 would reduce this impact to a less-than-significant level.

Mitigation Measure BIO-170: Avoid, Minimize, or Compensate for Impacts on Noncovered Special-Status Plant Species

DWR will evaluate all projects for their impacts on special-status plants, avoid or minimize impacts on species that occur on project sites, and compensate for impacts on species. All impacts on federally listed noncovered species, diamond-petaled California poppy, or caper-fruited tropidocarpum shall be avoided. Impacts on other special-status plant species shall be avoided to the extent feasible, and any unavoidable impacts shall be compensated for.

- DWR shall conduct surveys for the special-status plant species within and adjacent to all project sites. Special-status plant surveys required for project-specific permit compliance will be conducted during the planning phase to allow design of the individual restoration projects to avoid adverse modification of habitat for specified covered plants. The purpose of these surveys will be to verify that the locations of special-status plants identified in previous record searches or surveys are extant, identify any new special-status plant occurrences, and cover any portions of the project area not previously surveyed. The extent of mitigation of direct loss of or indirect effects on special-status plants will be based on these survey results.

- All surveys shall be conducted by qualified biologists using the using Guidelines for Conducting and Reporting Botanical Inventories for Federally Listed, Proposed and Candidate Plants (U.S. Fish and Wildlife Service 1996) and Protocols for Surveying and Evaluating Impacts to Special Status Native Plant Populations and Natural Communities (California Department of Fish and Game 2009) during the season that special-status plant species would be evident and identifiable, i.e., during their blooming season. Locations of special-status plants in proposed construction areas will be recorded using a GPS unit and flagged.

- The construction monitoring plan for the protection of covered fish, wildlife, and plant species, prepared by DWR before implementing an approved project, will provide for construction activity monitoring in areas identified during the planning stages and species/habitat surveys as having noncovered special-status plant species.

- Where surveys determine that a special-status plant species is present in or adjacent to a project site, direct and indirect impacts of the project on the species shall be avoided through the establishment of activity exclusion zones, within which no ground-disturbing activities shall take place, including construction of new facilities, construction staging, or other temporary work areas. Activity exclusion zones for special-status plant species shall be established around each occupied habitat site, the boundaries of which shall be clearly marked with standard orange plastic construction exclusion fencing or its equivalent. The establishment of activity exclusion zones shall not be required if no construction-related disturbances will occur within 250 feet of the occupied habitat site. The size of activity exclusion zones may be reduced through consultation with a qualified biologist and with concurrence from USFWS or CDFW based on project site-specific conditions.
Where avoidance of impacts on a special-status plant species is infeasible, DWR will compensate for loss of individuals or occupied habitat of a special-status plant species through the acquisition, protection, and subsequent management in perpetuity of other existing occurrences at a 2:1 ratio (occurrences affected: occurrences preserved). DWR will provide detailed information to USFWS and CDFW on the location of the preserved occurrences, quality of the preserved habitat, feasibility of protecting and managing the areas in perpetuity, responsible parties, and other pertinent information. If suitable occurrences of a special-status plant species are not available for preservation, then the project shall be redesigned to remove features that would result in impacts on that species.

Grassland Plants

One covered plant and 11 noncovered special-status plants occur in grasslands in the study area (Tables 12-2, 12-3, summarized in Table 12-1B-64). The only covered plant species occurring in grassland is Carquinez goldenbush. Carquinez goldenbush modeled habitat included hydrological features such as stream corridors on alluvium derived from the Montezuma Formation. Stream corridors (intermittent and perennial) that intersected these geologic units were selected and truncated at the point at which they encountered the upper elevation of intertidal marsh. The corridors were buffered 50 feet (15 meters) on either side in an effort to capture the estimated maximum extend of alluvium deposits in close proximity to the actual rivers/streams.

Full implementation of Alternative 1B would include the following conservation actions over the term of the BDCP to benefit covered grassland plants (BDCP Chapter 3, Section 3.3, Effects on Covered Wildlife and Plant Species).

- Protect three unprotected occurrences of the Carquinez goldenbush in Conservation Zones 1 and/or 11 (Objective CGB1.1, associated with CM3).
- Maintain and enhance occupied Carquinez goldenbush habitat to slow erosion and reverse degradation from livestock grazing (Objective CGB1.2, associated with CM11).

Of 78,047 acres of grasslands in the study area, Alternative 1B would adversely affect 3,037 acres, including 4 acres that are modeled habitat for Carquinez goldenbush. For 10 of the plants, no known occurrences would be affected. One of five Parry’s rough tarplant occurrences in the study area could be adversely affected by Alternative 1B. Table 12-1B-64 summarizes the acreage of grassland habitat in the study area and the number of occurrences of each special-status grassland plant in the study area.

*a This species actually occurs in upland woodland, a habitat that has not been mapped or quantified in the BDCP.

Impact BIO-171: Effects on Habitat and Populations of Grassland Plant Species

Alternative 1B, could have adverse effects on modeled habitat for Carquinez goldenbush. It could also have adverse effects on one occurrence of Carquinez goldenbush and one occurrence of Parry’s rough tarplant. Although Alternative 1B would have no expected effects on known occurrences of the other special-status plant species that occur in grasslands, the loss of 3,037 acres of grassland would have the potential to adversely affected undocumented populations of special-status grassland species.
The individual effects of each relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- **CM1 Water Facilities and Operations**: No modeled habitat for Carquinez goldenbush and no known occurrences of the 12 special-status grassland plants are within the proposed footprint for the Alternative 1B water conveyance facilities. About 758 acres of grassland habitat would be affected by construction of the water conveyance facilities. However, this grassland habitat primarily consists of small patches of herbaceous ruderal vegetation along levees that do not provide habitat for special-status grassland species. Therefore, under Alternative 1B, construction and operation of the water conveyance facilities would not affect the 12 special-status grassland plants.

- **CM2 Yolo Bypass Fisheries Enhancement**: Construction of the Yolo Bypass fisheries enhancements would remove 627 acres of grassland habitat. Yolo Bypass operations would result in more frequent and longer inundation of 1,597 acres of grasslands in the Yolo Causeway (CZ 2) that include habitat for one occurrence of Parry's rough tarplant. Parry's rough tarplant is a summer-blooming plant that occurs in areas subject to occasional inundation during the wet season, such as swales and seasonal wetlands. Increasing the frequency or duration of inundation may decrease the distribution in some areas by making some conditions too wet but would also expand the distribution into areas that may currently be too dry. Overall, changing the frequency and duration of inundation in the area of this occurrence should not result in a substantial change in the range of numbers of Parry's rough tarplant. Construction and operation of the Yolo Bypass fisheries enhancements would not affect modeled habitat for Carquinez goldenbush or known occurrences of other special-status grassland plants.

- **CM3 Natural Communities Protection and Restoration**: Alternative 1B would preserve 8,000 acres of grassland habitat, some of which may contain modeled habitat for Carquinez goldenbush. Protection of grassland habitat may also protect undiscovered occurrences of special-status plant species.

- **CM4 Tidal Natural Communities Restoration**: Tidal habitat restoration would permanently remove 1,122 acres of grassland habitat. Four acres of modeled habitat for Carquinez goldenbush along the eastern side of Suisun Marsh could be adversely affected, including part of one known occurrence. No other known occurrences of special-status grassland plants are within the hypothetical footprint of tidal restoration.

- **CM5 Seasonally Inundated Floodplain Restoration**: Construction of new floodplain levees would result in the loss of 85 acres of grassland habitat, periodic inundation of the floodplain would affect 513 acres of grassland habitat, and another 399 acres of grassland habitat would be converted to riparian habitat. However, no modeled habitat for Carquinez goldenbush or known occurrences of special-status grassland plants are present within areas proposed for floodplain restoration, and the affected grassland habitat consists of herbaceous ruderal vegetation that does not support special-status grassland plants. Therefore, floodplain restoration and construction of new floodplain levees would have no impacts on covered and noncovered grassland plants.

- **CM6 Channel Margin Enhancement**: No known occurrences of special-status grassland plants are present within areas proposed for channel margin habitat enhancement. Areas mapped as grassland along levees that would be affected by channel margin habitat enhancement are small patches of ruderal vegetation along levees that do not provide habitat for special-status
grassland species and are not modeled habitat for Carquinez goldenbush. Therefore, channel margin habitat enhancement would have no impacts on covered and noncovered grassland plants.

- **CM7 Riparian Natural Community Restoration**: No modeled habitat for Carquinez goldenbush or known occurrences of special-status grassland plants are present within areas proposed for riparian habitat enhancement. Therefore, riparian habitat enhancement would have no impacts on covered and noncovered grassland plants.

- **CM8 Grassland Natural Community Restoration**: Grassland restoration would restore 2,000 acres of grassland habitat. Restoration activities would take place in non-grasslands (ruderal habitat, cultivated land) or degraded grasslands. These areas do not currently provide habitat for special-status grassland plants. Therefore, grassland communities restoration would have no impacts on covered and noncovered grassland plants.

- **CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration**: Vernal pool complex includes vernal pools as well as the surrounding grassland matrix. Because the habitat to be restored would consist of areas of former vernal pool complex that have been leveled for cultivation, special-status grassland plants would not be present. Therefore, vernal pool and Alkali Seasonal Wetland complex restoration would not affect special-status grassland plants.

- **CM10 Nontidal Marsh Restoration**: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid grassland habitat and would have no impacts on covered and noncovered grassland plants.

- **CM18 Conservation Hatcheries**: Construction of the conservation hatcheries would remove 35 acres of grassland habitat. The removed habitat would consist of ruderal herbaceous vegetation that would not be likely to provide habitat for special-status grassland plants. Therefore, construction of the conservation hatcheries would not be expected to affect special-status grassland plants.

- **CM22 Avoidance and Minimization Measures**: Effects on Carquinez goldenbush potentially resulting from implementation of CM4 and potential effects on undiscovered populations of special-status grassland plants would be avoided or minimized though AMM11 Covered Plant Species, AMM2 Construction Best Management Practices and Monitoring, and AMM37 Recreation. Under AMM11, surveys for covered plant species would be performed during the planning phase of projects, and any impacts on populations of covered species would be avoided through project design or subsequently minimized though AMM2. AMM37 requires that new recreation trails would avoid populations of Carquinez goldenbush.

The primary effect of Alternative 1B on special-status grassland plants is the loss of potential (i.e., modeled) habitat for Carquinez goldenbush, including part of one known occurrence. Under AMM11, the occurrence would be surveyed to establish the population limits and to redesign the project to avoid affecting the populations, to the extent feasible. Protecting three unprotected occurrences of Carquinez goldenbush (Objective CGB1.1, associated with CM3) and maintaining and enhancing occupied Carquinez goldenbush (Objective CGB1.2, associated with CM11) would compensate for any residual effects. One occurrence of Parry’s rough tarplant would be affected by CM2, but the effect is not expected to be adverse. No known occurrences of the other special-status grassland plants would be affected.

The BDCP would have a potential beneficial effect on special-status grassland plants by protecting 8,000 acres of grassland habitat. To ensure that this habitat preservation would specifically benefit
Carquinez goldenbush, the plan proposes to protect at least three Carquinez goldenbush occurrences in CZ 1 and CZ 11 that are currently not protected and to maintain and enhance occupied Carquinez goldenbush habitat. The preservation of modeled or potential habitat, together with avoidance and minimization of impacts on species occurrences, would reduce any effects of BDCP implementation on covered grassland plants to a level that is no longer adverse.

**NEPA Effects:** The loss of modeled and occupied habitat for Carquinez goldenbush would be offset through CM3, CM8, and CM11. Therefore, implementation of Alternative 1B would result in no adverse effects on special-status grassland plants.

**CEQA Conclusion:** Because adverse effects on special-status grassland plant species would be avoided or compensated for, Alternative 1B would not result in a reduction in the range and numbers of covered and noncovered grassland plants, and this impact would be less than significant. No mitigation is required.

**Valley/Foothill Riparian Plants**

Two covered plants and two noncovered special-status plants occur in valley/foothill riparian habitat in the study area (Tables 12-2, 12-3, summarized in Table 12-1B-65). The valley/foothill riparian habitat model for Delta button-celery and slough thistle was mapped as all of the study area along the flood plain of the San Joaquin River between the levees from the Mossdale Bridge to Vernalis. Whether or not this modeled habitat is actually occupied by Delta button-celery and slough thistle is unknown; all known occurrences of these species within the area of modeled habitat are believed to be extirpated.

Full implementation of Alternative 1B would include the following conservation actions over the term of the BDCP to benefit covered valley/foothill riparian plants (BDCP Chapter 3, Section 3.3, Effects on Covered Wildlife and Plant Species).

- Protect and enhance two occurrences of delta button celery. If occurrences are not found in the Plan Area, establish self-sustaining occurrences of delta button celery for a total of two occurrences within the restored floodplain habitat on the mainstem of the San Joaquin River in Conservation Zone 7 between Mossdale and Vernalis. (Objective DBC1.1, associated with CM3 and CM11).

- Protect and enhance two occurrences of slough thistle. If occurrences are not found in the Plan Area, establish self-sustaining occurrences of slough thistle for a total of two occurrences within the 10,000 acres of restored floodplain on the mainstem of the San Joaquin River in Conservation Zone 7 between Mossdale and Vernalis (Objective ST1.1: associated with CM3 and CM11).

Of 17,966 acres of valley/foothill riparian habitat in the study area, Alternative 1B would adversely affect 896 acres, including 15 acres that are modeled habitat for Delta button-celery and 11 acres that are modeled habitat for slough thistle. Table 12-1B-65 summarizes the acreage of modeled habitat for Delta button-celery and slough thistle and the number of occurrences of each special-status grassland plant in the study area.

\(^a\) A portion of this acreage consists of alkali seasonal wetland.

\(^b\) A second occurrence is in alkali seasonal wetland.

### Impact BIO-172: Effects on Habitat and Populations of Valley/Foothill Riparian Plants

No extant occurrences of Delta button-celery, slough thistle, Northern California black walnut, or Wright’s trichocoronis are present in the study area. Therefore, no impacts on special-status valley/foothill riparian plants are expected. Modeled habitat for Delta button-celery and slough thistle, which may support undocumented occurrences of these species, would be affected by restoration of seasonally inundated floodplain.

The individual effects of each relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- **CM1 Water Facilities and Operations:** Construction of the water conveyance facilities would remove 91 acres of valley/foothill riparian habitat under Alternative 1B. However, no modeled habitat and no known occurrences of the four special-status valley/foothill riparian plants are within the proposed footprint for the Alternative 1B water conveyance facilities. Therefore, under Alternative 1B, construction and operation of the water conveyance facilities would not affect covered or noncovered special-status valley/foothill riparian plants.
**CM2 Yolo Bypass Fisheries Enhancement:** Construction and operation of the Yolo Bypass fisheries enhancements would adversely affect 378 acres of valley/foothill riparian habitat. However, no modeled habitat and no known occurrences of the four special-status valley/foothill riparian plants are within the hypothetical footprint for construction or operation of the Yolo Bypass fisheries enhancements. Therefore, construction and operation of the Yolo Bypass fisheries enhancements would not affect the covered or noncovered valley/foothill riparian plants.

**CM3 Natural Communities Protection and Restoration:** Alternative 1B would protect 552 acres of existing valley/foothill riparian forest in CZ 7. This action would have no substantial effects on special-status valley/foothill plants because no extant occurrences of special-status valley/foothill plants are present in the study area.

**CM4 Tidal Natural Communities Restoration:** Tidal habitat restoration would inundate 552 acres of valley/foothill riparian habitat. However, no modeled habitat and no known occurrences of the four special-status valley/foothill riparian plants are within the hypothetical footprint for tidal restoration. Therefore, tidal restoration would not affect the covered or noncovered valley/foothill riparian plants.

**CM5 Seasonally Inundated Floodplain Restoration:** Floodplain restoration levee construction would remove 15 acres of modeled habitat for Delta button-celery along the San Joaquin River in CZ 7. In addition, floodplain restoration would result in more frequent and longer inundation of 18 acres of modeled habitat for Delta button-celery in this area. The area affected contains one historic occurrence of Delta button celery. This occurrence is considered to be extirpated, because all habitat for Delta button-celery at his location has been converted to agriculture (California Department of Fish and Wildlife 2013). Therefore, Alternative 1B would not have an adverse effect on Delta button celery in CZ 7.

The BDCP proposes to benefit Delta button-celery at this location by restoring 5,000 acres of valley/foothill riparian habitat and re-introducing two occurrences of Delta button-celery. Although Delta button celery occurs in riparian habitat, it is not associated with woodland or scrub habitats; rather, it occurs in alkali seasonal wetlands in floodplains, which may or may not also contain adjacent woody riparian habitat. Restoring habitat for Delta button-celery may not be compatible with restoring woody riparian habitat. In addition, establishing new populations of Delta button-celery is an untried, unproven procedure and may not be feasible. Therefore, any beneficial effects on Delta button-celery would be speculative.

Floodplain restoration levee construction would remove 11 acres of modeled habitat for slough thistle and would result in more frequent and longer inundation of 6 acres of modeled habitat for slough thistle along the San Joaquin River in CZ 7. However, the BDCP would allow up to 50 acres of modeled habitat to be converted to riparian habitat. Whether the affected modeled habitat is actually occupied by slough thistle is not known; however, of two historic occurrences of slough thistle present in the study area, only one is considered to be extirpated (California Department of Fish and Wildlife 2013). The BDCP would protect and enhance two occurrences of slough thistle. If occurrences are not found in the study area, then two self-sustaining occurrences of slough thistle would be established using locally-sourced genetic material for a total of two occurrences within the restored floodplain habitat on the main stem of the San Joaquin River in Conservation Zone 7 between Mossdale and Vernalis. Establishing new populations of slough thistle is an untried, unproven procedure and may not be feasible. Therefore, any beneficial effects on slough thistle would be speculative.
One historic occurrence of Wright’s trichocoronis in the study area near Lathrop (CZ 7) could also be affected by floodplain restoration. The occurrence is presumed to be extant because the presence or absence of suitable habitat has not been verified by field surveys (California Department of Fish and Wildlife 2013). However, the species has not been observed at this location for nearly a century, and habitat for Wright’s trichocoronis, which would have been similar to that for Delta button celery and slough thistle, no longer appears to be present in aerial photographs of the area. Therefore, Alternative 1B would not be expected to have an adverse effect on Wright’s trichocoronis.

- **CM6 Channel Margin Enhancement**: No modeled habitat or occurrences of special-status valley/foothill riparian plants are present within areas proposed for channel margin habitat enhancement. Therefore, channel margin habitat enhancement would have no impacts on covered and noncovered valley/foothill riparian plants.

- **CM7 Riparian Natural Community Restoration**: No extant occurrences of special-status valley/foothill riparian plants are present within areas proposed for riparian habitat restoration. Therefore, riparian habitat restoration would have no impacts on covered and noncovered valley/foothill riparian plants.

- **CM8 Grassland Natural Community Restoration**: No occurrences of special-status valley/foothill riparian plants are present within areas proposed for grassland communities restoration. Therefore, grassland communities restoration would have no impacts on covered and noncovered valley/foothill riparian plants.

- **CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration**: No occurrences of special-status valley/foothill riparian plants are present within areas proposed for vernal pool and alkali seasonal wetland complex restoration. Therefore, vernal pool and alkali seasonal wetland complex restoration would have no impacts on covered and noncovered valley/foothill riparian plants.

- **CM10 Nontidal Marsh Restoration**: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid valley/foothill riparian habitat and would have no impacts on covered and noncovered valley/foothill riparian plants.

- **CM22 Avoidance and Minimization Measures**: Effects on Delta button-celery and slough thistle potentially resulting from implementation of CM5 would be avoided or minimized through AMM11 Covered Plant Species and AMM2 Construction Best Management Practices and Monitoring. Under AMM11, surveys for covered plant species would be performed during the planning phase of projects, and any impacts on populations of covered species would be avoided through project design or subsequently minimized through AMM2.

Because no extant occurrences of special-status valley/foothill riparian plants are known to occur in the study area, Alternative 1B is not expected to adversely affect any special-status valley/foothill riparian plants. Modeled habitat for both Delta button-celery and slough thistle would be affected. Under AMM11, surveys for covered plants would be performed during the planning phase for floodplain restoration. If Delta button-celery or slough thistle were found to be present in the floodplain restoration area, then the project would be designed to avoid impacts on the populations. Therefore, Alternative 1B would not have an adverse effect on these species.

The BDCP proposes to benefit Delta button-celery and slough thistle by restoring 5,000 acres of valley/foothill riparian habitat and re-introducing two occurrences of both species. Establishing
new populations of Delta-button-celery or slough thistle would be a beneficial effect. However, establishing new populations is an untried, unproven procedure and may not be feasible.

**NEPA Effects:** Implementing the BDCP under Alternative 1B would not have an adverse effect on special-status valley/foothill riparian plant species.

**CEQA Conclusion:** Alternative 1B would not result in a reduction in the range and numbers of covered and noncovered valley/foothill riparian plants, and this impact would be less than significant. No mitigation is required.

**Tidal Wetland Plants**

Seven covered plants and one noncovered special-status plant occur in tidal wetlands in the study area (Tables 12-2, 12-3, summarized in Table 12-1B-66). Five tidal wetland habitat models were developed for the seven covered plant species occurring in tidal wetland habitat.

Modeled habitat for Mason’s lilaeopsis and Delta mudwort was mapped as areas within 10 feet (3 meters) on either side of the landward boundary of tidal perennial aquatic land cover type, which was obtained from the BDCP GIS vegetation data layer.

The side-flowering skullcap model mapped the distribution of suitable habitat in the study area according to the species’ habitat association with woody riparian habitat. The model selected Delta riparian vegetation types providing the habitat characteristics that side-flowering skullcap seems to require, namely, woody substrate in freshwater tidal areas. The model included vegetation subunits of the BDCP Valley Riparian natural community characterized by California dogwood, white alder, and arroyo willow.

The modeled habitat for soft bird’s-beak consisted of pickleweed- and saltgrass-dominated vegetation units located west of the Antioch Bridge. Modeled habitat for these two plant species was mapped as areas within 10 feet (3 meters) on either side of the landward boundary of tidal perennial aquatic land cover types. The model used all Tidal Brackish Emergent Wetland polygons that were limited by specific vegetation units that are known to be closely associated with soft bird’s-beak habitat.

Habitat for Delta tule pea and Suisun Marsh aster was modeled separately based on the salinity of the water. For the tidal freshwater emergent wetland BDCP land cover type, modeled habitat was mapped as the area within 10 feet (3 meters) of the landward side of the landward boundary, exclusively where this land cover type is adjacent to grassland, vernal pool complex, valley/foothill riparian, or cultivated land habitats cover types. For brackish water areas in and near Suisun Marsh, the model used all tidal brackish emergent wetland polygons within an elevation range of 7 to 10 feet (2 to 3 meters) to capture elevations 1 foot (30 centimeters) below intertidal to 2 feet (60 centimeters) above intertidal.

The modeled habitat for Suisun thistle in and near Suisun Marsh consists of all tidal brackish emergent wetland polygons with the appropriate vegetation. This included vegetation units dominated by saltscale, saltgrass, pickleweed, and broad-leaved peppergrass.

Full implementation of Alternative 1B would include the following conservation actions over the term of the BDCP to benefit covered tidal wetland plants (BDCP Chapter 3, Section 3.3, *Effects on Covered Wildlife and Plant Species*).
• No net loss of Mason’s lilaeopsis and delta mudwort occurrences within restoration sites, or
within the area of affected tidal range of restoration projects (Objective DMW/ML1.1, associated
with CM4 and CM11).

• No net loss of Delta tule pea and Suisun Marsh aster occurrences within restoration sites
(Objective DTP/SMA1.1, associated with CM4 and CM11).

• Restore tidal inundation to wetlands in the Hill Slough Ecological Reserve and to the ponded
area at Rush Ranch (Objective SBB/SuT1.1, associated with CM4).

• Complete seed banking of all existing Suisun Marsh populations and the representative genetic
diversity using accepted seed banking protocols (Objective SBB/SuT1.2, associated with CM11).

• Establish a cultivated population of Suisun thistle from wild seed using accepted seed collection
protocols (Objective SBB/SuT1.3, associated with CM11).

• Establish two occurrences of Suisun thistle in Conservation Zone 11 (Objective SBB/SuT1.4,
associated with CM11).

Of 17,357 acres of tidal wetlands in the study area, Alternative 1B would affect 28 acres, including
areas that are modeled habitat for Mason’s lilaeopsis, Delta mudwort, side-flowering skullcap, Delta
tule pea, Suisun Marsh aster, soft bird’s-beak, and Suisun thistle. Known occurrences of all of these
species would be affected. In addition, four occurrences of Bolander’s water-hemlock, a noncovered
special-status plant, could be affected by tidal habitat restoration. Table 12-1B-66 summarizes the
acreage of modeled habitat for covered tidal wetland species and the number of occurrences of each
special-status tidal wetland plants in the study area.

## Impact BIO-173: Effects on Habitat and Populations of Tidal Wetland Plants

Alternative 1B would have adverse effects on tidal marsh special-status plants through implementation of CM1, CM2, CM4, and CM5. No adverse effects are expected from implementation of CM3, CM6, CM7, CM8, and CM9.

The individual effects of each relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.

- **CM1 Water Facilities and Operations**: Construction of the Alternative 1B water conveyance facilities would remove 39 acres of modeled habitat for delta mudwort and Mason's lilaeopsis, 7 acres of modeled habitat for side-flowering skullcap, and 4 acres of modeled habitat for Delta tule pea and Suisun Marsh aster. The extent to which modeled habitat is actually occupied by these species is not known; however, three occurrences of Mason's lilaeopsis, two occurrences
of Delta tule pea, and two occurrences of side-flowering skullcap in the study area could be affected by construction impacts. No known occurrences of the other covered and noncovered tidal wetland species would be affected by construction of the water conveyance facilities.

- **CM2 Yolo Bypass Fisheries Enhancement**: Construction of the Yolo Bypass fisheries enhancements would remove 5 acres of modeled habitat for Mason’s lilaeopsis and delta mudwort. The extent to which modeled habitat is actually occupied by these species is not known; however, no known occurrences in the study area would be affected. Yolo Bypass operations would result in more frequent and longer inundation of 8 acres of modeled habitat Delta tule peas and Suisun Marsh aster. Two occurrences of Suisun Marsh aster would be affected by Yolo Bypass operations. Habitat for these species is normally periodically inundated or saturated; therefore, a small increase in the frequency and duration of periodic inundation of the habitat would not be expected to have a substantial effect.

- **CM3 Natural Communities Protection and Restoration**: The BDCP proposes restoring or creating 20 linear miles of transitional tidal areas within other natural communities that would be created or restored, including 6,000 acres of tidal brackish emergent wetland and 24,000 acres of tidal freshwater emergent wetland. In addition, the habitat and ecosystem functions of these areas would be maintained and enhanced. The BDCP does not specifically propose to protect any occurrences of tidal wetland plants nor does it propose active restoration of affected habitat or occurrences. Instead, the BDCP assumes that the 20 linear miles of restored transitional tidal areas will be passively colonized by the covered tidal wetland plants.

- **CM4 Tidal Natural Communities Restoration**: Tidal habitat restoration would permanently remove 6 acres of modeled habitat for Mason’s lilaeopsis and Delta mudwort. Habitat loss would occur through conversion of the species habitat (at and immediately above the tidal zone in marshes and along rivers and streams) to inundated tidal habitat. The extent to which modeled habitat is actually occupied by the species is not known; however, 14 of 181 known occurrences of Mason’s lilaeopsis and 3 of 58 known occurrences of delta mudwort in the study area could be affected by tidal habitat restoration.

Tidal habitat restoration would remove 4 acres of modeled habitat for side-flowering skullcap. Whether the affected modeled habitat is actually occupied by side-flowering skullcap is not known; however, none of the 12 known occurrences in the study area would be affected.

Tidal habitat restoration would remove 2 acres of modeled habitat for Delta tule pea and Suisun Marsh aster. However, the BDCP would allow up to 50 acres of modeled habitat to be removed. Habitat loss would result from conversion of the species habitat (at and immediately above the tidal zone in marshes and along rivers and streams) to inundated tidal habitat. The extent to which modeled habitat is actually occupied by the species is not known; however, 26 of 106 known occurrences of Delta tule pea and 24 of 164 occurrences of Suisun Marsh aster in the study area would be affected.

Tidal habitat restoration could affect 73 acres of modeled habitat for soft bird’s-beak and Suisun thistle, including 1.3 acres of critical habitat. The extent to which modeled habitat is actually occupied by the species is not known; however, seven of 13 known occurrences of soft bird’s-beak in the study area could be affected. None of the four known occurrences of Suisun thistle in the study area would be affected.

Tidal habitat restoration could affect three of eight known occurrences of Bolander’s water-hemlock, a noncovered special-status species in the study area. Because Bolander’s water-
hemlock occurs in tidal marsh, it may benefit from tidal marsh restoration. However, site
preparation, earthwork, and other site activities could adversely affect Bolander’s water-
hemlock through direct habitat removal.

- **CM5 Seasonally Inundated Floodplain Restoration**: Floodplain restoration levee construction
would remove 3 acres of modeled habitat for Mason’s lilaeopsis and delta mudwort and 2 acres
of modeled habitat for side-flowering skullcap. No known occurrences of these species in the
study area would be affected by floodplain restoration.

Floodplain restoration would result in more frequent and longer inundation of 2 acres of
modeled habitat for Mason’s lilaeopsis and delta mudwort, 18 acres of modeled habitat for side-
flowering skullcap, and 1 acre of modeled habitat for Delta tule peas and Suisun Marsh aster. No
known occurrences of these species in the study area would be affected by periodic inundation
of restored floodplain habitat. Habitat for these species is normally periodically inundated or
saturated; therefore, a small increase in the frequency and duration of periodic inundation of the
habitat would not be expected to have a substantial effect.

- **CM6 Channel Margin Enhancement**: Effects of channel margin enhancement were not analyzed
separately from the effects of tidal habitat restoration. Channel margin enhancement would
have adverse effects on tidal wetland plants through direct removal and habitat modification.
However, it would have beneficial effects on these species by improving the habitat functions for
these species as a result of riprap removal and creation of floodplain benches. Side-flowering
skullcap would benefit from installation of large woody material, which it appears to colonize.

- **CM7 Riparian Natural Community Restoration**: Riparian habitat restoration is not expected to
adversely affect special-status tidal wetland plants. Preparatory work that involves habitat
disturbance would occur during implementation of CM4 and CM5. Riparian plantings carried out
for CM7 would be placed in floodplain areas, not in tidal wetlands.

- **CM8 Grassland Natural Community Restoration**: No tidal wetlands or occurrences of special-
status tidal wetland plants are present within areas proposed for grassland communities
restoration. Therefore, grassland communities restoration would have no impacts on covered
and noncovered tidal wetland plants.

- **CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration**: No tidal wetlands or
occurrences of special-status tidal wetland plants are present within areas proposed for vernal
pool and alkali seasonal wetland complex restoration. Therefore, vernal pool and alkali seasonal
wetland complex restoration would have no impacts on covered and noncovered tidal wetland
plants.

- **CM10 Nontidal Marsh Restoration**: Nontidal marsh restoration would take place through
conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid tidal wetland
habitat and would have no impacts on covered and noncovered tidal wetland plants.

- **CM22 Avoidance and Minimization Measures**: Effects on covered tidal wetland plants potentially
resulting from implementation of CM1, CM2, CM4, and CM5 would be avoided or minimized
though **AMM11 Covered Plant Species, AMM2 Construction Best Management Practices and
Monitoring, AMM30 Transmission Line Design and Alignment Guidelines, and AMM37 Recreation**.

Under AMM11, surveys for covered plant species would be performed during the planning
phase of projects, and any impacts on populations of covered species would be avoided through
project design or subsequently minimized though AMM2. In addition, AMM11 contains specific
guidance to avoid adverse modification of any of the primary constituent elements for Suisun
Alternative 1B
Terrestrial Biological Resources

Thistle or soft bird’s-beak critical habitat. AMM30, which specifies that proposed transmission line poles and towers would be sited to avoid sensitive terrestrial and aquatic habitats, to the maximum extent feasible, would avoid some impacts on Mason’s lilaeopsis, Delta tule pea, and side-flowering skullcap. AMM37 requires that new recreation trails avoid populations of covered tidal wetland plants.

In summary, the GIS analysis indicates that Alternative 1B would result in the loss of modeled habitat for all of the covered species and result in adverse effects on known occurrences of most of the special-status plants occurring in tidal wetlands. However, the BDCP predicts that habitat restoration activities would greatly expand the amount of habitat available to each of these species, offsetting any potential loss of habitat or occurrences resulting from covered activities.

Delta mudwort could lose 53 acres of modeled habitat (0.9%), including all or part of three occurrences. The BDCP predicts that tidal habitat restoration activities proposed under CM4 (Objectives TBEWNC1.1 and TFEWNC1.1) would increase the extent of habitat available for colonization by Delta mudwort, which could offset this habitat loss. Channel margin enhancement (CM6) and riparian natural community restoration (CM7) will also consider the potential for creating habitat for Delta mudwort; creation of suitable habitat under these measures could also help offset this habitat loss. Although active restoration of this species is not proposed, the BDCP predicts that natural expansion of populations into the restored habitat would take place and result in no net loss of occurrences (Objective DMW/ML1.1, associated with CM11). Post-implementation monitoring of affected occurrences and occurrences in reserve lands would be done to confirm that no net loss of occurrences has been achieved (Monitoring Action CM11-21, associated with CM11).

Mason’s lilaeopsis could lose 53 acres of modeled habitat (0.9%), including all or part of three occurrences. The BDCP predicts that tidal habitat restoration activities proposed under CM4 (Objectives TBEWNC1.1 and TFEWNC1.1) would increase the extent of habitat available for colonization by Mason’s lilaeopsis, which could offset this habitat loss. Channel margin enhancement (CM6) and riparian natural community restoration (CM7) will also consider the potential for creating habitat for Mason’s lilaeopsis; creation of suitable habitat under these measures could also help offset this habitat loss. Although active restoration of this species is not proposed, the BDCP predicts that natural expansion of populations into the restored habitat would take place and result in no net loss of occurrences (Objective DMW/ML1.1, associated with CM11). Post-implementation monitoring of affected occurrences and occurrences in reserve lands would be done to confirm that no net loss of occurrences has been achieved (Monitoring Action CM11-21, associated with CM11).

Delta tule pea could lose 5 acres of modeled habitat (0.08%), including all or part of 28 occurrences. The BDCP predicts that tidal habitat restoration activities proposed under CM4 (Objectives TBEWNC1.1 and TFEWNC1.1) would increase the extent of habitat available for colonization by Delta tule pea, which could offset this habitat loss. Channel margin enhancement (CM6) and riparian natural community restoration (CM7) would also consider the potential for creating habitat for Delta tule pea; creation of suitable habitat under these measures could also help offset this habitat loss. Although active restoration of this species is not proposed, the BDCP predicts that natural expansion of populations into the restored habitat would take place and result in no net loss of occurrences (Objective DTP/SMA1.1, associated with CM11). Post-implementation monitoring of affected occurrences and occurrences in reserve lands would be done to confirm that no net loss of occurrences has been achieved (Monitoring Action CM11-22, associated with CM11).
Suisun Marsh aster could lose 5 acres of modeled habitat (0.08%), including all or part of 27 occurrences. The BDCP predicts that tidal habitat restoration activities proposed under CM4 (Objectives TBEWNC1.1 and TFEWNC1.1) would increase the extent of habitat available for colonization by Suisun Marsh aster, which could offset this habitat loss. Channel margin enhancement (CM6) and riparian natural community restoration (CM7) will also consider the potential for creating habitat for Suisun marsh aster; creation of suitable habitat under these measures could also help offset this habitat loss. Although active restoration of this species is not proposed, the BDCP predicts that natural expansion of populations into the restored habitat would occur and result in no net loss of occurrences (Objective DTP/SMA1.1, associated with CM11). Post-implementation monitoring of affected occurrences and occurrences in reserve lands would be done to confirm that no net loss of occurrences has been achieved (Monitoring Action CM11-22, associated with CM11).

All four of these species (Delta mudwort, Mason’s lilaeopsis, Delta tule pea, and Suisun Marsh aster) are widespread in the study area with many occurrences. Habitat modification and loss are the primary stressors that are responsible for their decline and that currently limit their distribution and abundance. Therefore, restoring large areas of habitat and improving habitat functions for these species would provide a reasonable expectation that the distribution and abundance of these species would also improve. Because a relatively small amount of modeled habitat would be adversely affected (less than 1% of the total), it is likely that the initial adverse effects of covered activities on these species would be offset and that the overall effect of Alternative 1B on these species would not be adverse.

Side-flowering skullcap could lose 13 acres of modeled habitat (0.5%), including all or part of two occurrences. One occurrence would be avoided through implementation of AMM30. The location of a second potentially affected occurrence, which was last observed in 1892, is not known precisely. Under AMM11, this occurrence would be surveyed for, and because this is a tidal freshwater wetland species, avoidance of the habitat during project construction would be highly likely. The BDCP predicts that tidal habitat restoration activities proposed under CM4 (Objectives TBEWNC1.1 and TFEWNC1.1) would increase the extent of habitat available for colonization by side-flowering skullcap, which could offset this habitat loss. Channel margin enhancement (CM6) and riparian natural community restoration (CM7) will also consider the potential for creating habitat for side-flowering skullcap; creation of suitable habitat under these measures could also help offset this habitat loss. No active restoration of this species is proposed, and no post-implementation monitoring of affected occurrences and occurrences in reserve lands would be done. Because impacts on occurrences of side-flowering skullcap would be avoided, and because loss of modeled habitat for the species would be offset through restoration, the overall effect of Alternative 1B on this species would not be adverse.

Soft bird’s-beak could lose 73 acres of modeled habitat (6%), including all or part of seven occurrences. The BDCP predicts that tidal habitat restoration activities proposed under CM4 (Objectives TBEWNC1.1 and TFEWNC1.1) would increase the extent of habitat available for colonization by soft bird’s-beak, which could offset this habitat loss. Tidal restoration in the Hill Slough Ecological Reserve would be done to increase potential habitat there for soft bird’s-beak (Objective SBB/SuT1.1, associated with CM4). In addition, activities to control invasive plants and manage livestock in tidal marsh habitat under CM11 could enhance habitat for soft bird’s-beak. Although no active restoration of this species is proposed, post-implementation monitoring of soft bird’s-beak occurrences in proximity to tidal restoration sites would be done to confirm that occurrences are stable or increasing (Monitoring Action CM11-22, associated with CM11).
bird’s-beak has a restricted distribution in the study area with highly localized occurrences, and
habitat modification is the primary factor responsible for the species’ decline and limiting the
species’ distribution and abundance. Improving habitat functions for this species would provide a
reasonable expectation that the distribution and abundance of soft bird’s-beak would also improve.
Although a substantial amount of modeled habitat could be affected, the primary habitat for soft
bird’s-beak is high tidal brackish marsh, and the affected habitat is low tidal brackish marsh.
Therefore, it is likely that the overall effect of Alternative 1B on this species would not be adverse.

Suisun thistle could lose 73 acres of modeled habitat (6%), although no occurrences would be
affected. The BDCP predicts that tidal habitat restoration activities proposed under CM4 (Objectives
tBEWNC1.1 and TFEWNC1.1) would increase the extent of habitat available for colonization by
Suisun thistle, which could offset this habitat loss. Tidal restoration in the Hill Slough Ecological
Reserve and at Rush Ranch would be done to increase potential habitat there for Suisun thistle
(Objective SBB/SuT1.1, associated with CM4). In addition, activities to control invasive plants and
manage livestock in tidal marsh habitat under CM11 could enhance habitat for Suisun thistle. In
addition, two new occurrences of Suisun thistle would be established in CZ 11 (Objective
SBB/SuT1.4, associated with CM11). Post-implementation monitoring of Suisun thistle occurrences
in proximity to tidal restoration sites would be done to confirm that occurrences are stable or
increasing (Monitoring Action CM11-22, associated with CM11). Habitat restoration, enhancement
of habitat functions, and establishment of new occurrences would offset any potential loss of
modeled habitat for Suisun Marsh thistle.

Three occurrences of Bolander’s water-hemlock could be affected. Although the extent of potential
habitat affected was not determined, it would be comparable to that for Delta tule pea and Suisun
Marsh aster (5 acres). Tidal habitat restoration activities proposed under CM4 (Objectives
tBEWNC1.1 and TFEWNC1.1) could increase the extent of habitat available for colonization by
Bolander’s water-hemlock, which could offset this habitat loss. Because only a few scattered
occurrences of Bolander’s water-hemlock are present in the study area, there is no reasonable
expectation that habitat restoration without active species-specific restoration activities would
result in the establishment of new occurrences to offset the losses. Also, because Bolander’s water-
hemlock is a noncovered species, the species protections and occurrence monitoring afforded to
covered species under the BDCP would not apply to this species. Therefore, the effects of Alternative
1B on Bolander’s water hemlock could be adverse.

**NEPA Effects:** The loss of modeled and occupied habitat for special-status tidal wetland plants
would be offset through tidal habitat restoration (CM4). Therefore, implementation of Alternative
1B would result in no adverse effects on seven of eight special-status grassland plants in the study
area. Alternative 1B would result in a reduction in the range and numbers of Bolander’s water-
hemlock, which would be an adverse effect. Adverse effects on Bolander’s water-hemlock could be
avoided or offset through implementation of Mitigation Measure BIO-170, *Avoid, Minimize, or
Compensate for Impacts on Noncovered Special-Status Plant Species.*

**CEQA Conclusion:** Because loss of occurrences and modeled habitat for covered tidal habitat plant
species would be offset through habitat restoration, impacts on covered tidal wetland plants as a
result of implementing Alternative 1B would not be significant. However, the loss of Bolander’s
water-hemlock populations in CZ 11 would result in a reduction in the range and numbers of this
species and would be a significant impact. Implementation of Mitigation Measure BIO-170 would
reduce this impact to a less-than-significant level.
Mitigation Measure BIO-170: Avoid, Minimize, or Compensate for Impacts on Noncovered Special-Status Plant Species

Please see Mitigation Measure BIO-170 under Impact BIO-170.

Inland Dune Plants

Impact BIO-174: Effects on Habitat and Populations of Inland Dune Plants

Alternative 1B would have no adverse effects on inland dune plants (Table 12-1B-67). No construction activities or habitat restoration would take place where the species occur. No specific actions to benefit inland dune species are proposed.

NEPA Effects: Implementing the BDCP under Alternative 1B would not affect special-status inland dune plant species.

CEQA Conclusion: Implementation of Alternative 1B would have no impacts on inland dune species. No mitigation is required.

Nontidal Wetland Plants

No covered plant species occur in nontidal wetlands in the study area; however, six noncovered special-status plant species occur in nontidal wetlands in the study area. Table 12-1B-68 summarizes the acreage of nontidal wetland habitat in the study area and the number of occurrences of each special-status nontidal wetland plant in the study area.

a Also occurs in valley/foothill riparian habitat.

Impact BIO-175: Effects on Habitat and Populations of Nontidal Wetland Plants

Under Alternative 1B, known occurrences of bristly sedge and woolly rose-mallow are within the proposed footprint for the water conveyance facilities or within the hypothetical footprint for restoration activities and would be adversely affected. Alternative 1B would have no adverse effects on watershed, eel-grass pondweed or marsh skullcap.

The individual effects of each relevant conservation measure are addressed below. A summary statement of the combined impacts and NEPA and CEQA conclusions follows the individual conservation measure discussions.
CM1 Water Facilities and Operations: Construction of the Alternative 1B water conveyance facilities would adversely affect three noncovered special-status plants occurring in nontidal wetlands. Two occurrences of bristly sedge in CZ 4 and CZ 5, including approximately 1.54 acres of occupied habitat, would be affected by construction of the water conveyance facilities. Eleven occurrences of woolly rose-mallow would be affected. Five occurrences would be affected by construction of the intake structures, and six occurrences would be affected by siphon works areas and borrow/spoils sites. Two occurrences of Sanford’s arrowhead would be affected.

CM2 Yolo Bypass Fisheries Enhancement: No known occurrences of special-status nontidal wetland plants are present in the hypothetical footprint for construction or operation of the Yolo Bypass fisheries enhancements. Therefore, construction and operation of the Yolo Bypass fisheries enhancements would not affect special-status nontidal marsh plants.

CM3 Natural Communities Protection and Restoration: No specific natural communities protection is proposed for nontidal wetlands under the BDCP. Therefore, no occurrences of special-status nontidal plants are proposed for protection.

CM4 Tidal Natural Communities Restoration: One known occurrence of Sanford’s arrowhead in CZ 2 and one occurrence of woolly rose-mallow in CZ 7 are present within areas proposed for tidal habitat restoration and could be lost as a result of habitat conversion. Therefore, tidal habitat restoration would have an adverse effect on these species. No other special-status tidal wetland plants would be affected.

CM5 Seasonally Inundated Floodplain Restoration: No known occurrences of special-status nontidal wetland plants are present within areas proposed for floodplain restoration. Therefore, floodplain restoration and construction of new floodplain levees would have no impacts on special-status nontidal wetland plants.

CM6 Channel Margin Enhancement: No known occurrences of special-status nontidal wetland plants are present within areas proposed for channel margin habitat enhancement. Therefore, channel margin habitat enhancement would have no impacts on special-status nontidal wetland plants.

CM7 Riparian Natural Community Restoration: No known occurrences of special-status nontidal wetland plants are present within areas proposed for riparian habitat restoration. Therefore, riparian habitat restoration would have no impacts on special-status nontidal wetland plants.

CM8 Grassland Natural Community Restoration: No known occurrences of special-status nontidal wetland plants are present within areas proposed for grassland communities restoration. Therefore, grassland communities restoration would have no impacts on special-status nontidal wetland plants.

CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration: No known occurrences of special-status nontidal wetland plants are present within areas proposed for vernal pool and alkali seasonal wetland complex restoration. Therefore, vernal pool and alkali seasonal wetland complex restoration would have no impacts on special-status nontidal wetland plants.

CM10 Nontidal Marsh Restoration: Nontidal marsh restoration would take place through conversion of cultivated lands. Therefore, nontidal marsh restoration would avoid existing nontidal marsh and would have no adverse effects on special-status nontidal wetland plants. The BDCP may benefit nontidal wetland species by creating 400 acres of nontidal freshwater marsh, including components of nontidal perennial aquatic and nontidal freshwater perennial...
emergent wetland communities, and by maintaining and enhancing the habitat functions of protected and created nontidal wetland habitats for covered and other native species. However, no specific actions to benefit noncovered species are proposed.

Under Alternative 1B, 1,500 acres of nontidal marsh would be restored (Objective NFEW/NPANC1.1, addressed under CM10). However, these wetlands would be restored primarily as habitat for giant garter snake. These habitat restoration activities would be unlikely to expand the amount of habitat available to bristly sedge, woolly rose-mallow, and Sanford’s arrowhead, potential loss of habitat or occurrences resulting from covered activities would not be compensated for. Moreover, because special-status nontidal wetland plant species are not covered under the BDCP, the species protections afforded to covered species under CM22 do not apply to these species, and the effects of Alternative 1B on these species would be adverse.

**NEPA Effects:** Implementation of the BDCP under Alternative 1B could result in a reduction in the range and numbers of bristly sedge, woolly rose-mallow, and Sanford’s arrowhead, three noncovered nontidal wetland species, which would be an adverse effect. Adverse effects on these species could be avoided or offset through implementation of Mitigation Measure BIO-170.

**CEQA Conclusion:** Under Alternative 1B, construction of the water conveyance facilities and tidal habitat restoration could result in a reduction in the range and numbers of bristly sedge, woolly rose-mallow, and Sanford’s arrowhead. Tidal habitat restoration could result in a reduction in the range and numbers of Sanford’s arrowhead and woolly rose-mallow. These impacts would be significant. Implementation of Mitigation Measure BIO-170 would reduce these impacts to a less-than-significant level.

**Mitigation Measure BIO-170: Avoid, Minimize, or Compensate for Impacts on Noncovered Special-Status Plant Species**

Please see Mitigation Measure BIO-170 under Impact BIO-170.

**General Terrestrial Biology Effects**

**Wetlands and Other Waters of the United States**

Alternative 1B actions would both permanently and temporarily remove or convert wetlands and open water that is potentially jurisdictional as regulated by the USACE under Section 404 of the CWA. The following two impacts address the project-level effects of CM1 on these potential wetlands and waters, and the programmatic-level effects of other relevant conservation actions (CM2–CM10). CM11–CM22 would not directly result in loss or conversion of wetlands or other waters of the United States. The methods used to conduct these analyses are described in Section 12.3.2.4 of this chapter.

**Impact BIO-176: Effects of Constructing Water Conveyance Facilities (CM1) on Wetlands and Other Waters of the United States**

Construction of the Alternative 1B water conveyance facilities would both temporarily and permanently remove potential wetlands and other waters of the United States as regulated by Section 404 of the CWA (Table 12-1B-69). Based on the methodology used to conduct this analysis, the losses would occur at pipeline, canal and intake areas, borrow/spoil storage sites, transmission corridors, forebay site, and multiple temporary work areas associated with the construction activity.
The permanent open water and wetland losses (346 acres) would occur at scattered locations along the water conveyance facility alignment, with the majority caused by construction of Alternative 1B's five intake structures along the eastern bank of the Sacramento River between Freeport and Courtland in the north Delta (including associated spoil/borrow areas), along the entire canal route in the east Delta, and at the Byron forebay site in the south Delta. The temporary open water and wetland effects (206 acres) would also occur mainly at the five intake construction sites along the eastern bank of the Sacramento River, and at temporary siphon work areas where the canal crosses under eastern Delta sloughs and waterways.

**NEPA Effects:** The permanent and temporary loss of these potential jurisdictional wetlands as a result of constructing Alternative 1B water conveyance facilities would be a substantial effect if not compensated by wetland protection and/or restoration. This loss would represent a removal of federally protected wetlands as defined by Section 404 of the CWA. However, Alternative 1B includes conservation measures (CM4 and CM10) that would restore and protect large acreages of both tidal and nontidal wetlands and open water in the study area.

Through the course of the BDCP restoration program, Alternative 1B would restore 65,000 acres of tidal and 1,200 acres of nontidal wetland or open water. Impacts on wetlands from CM1 construction would occur in the first 10 years after BDCP approval. Approximately 19,550 acres of this wetland restoration would occur during this time period, thereby offsetting the impacts of CM1 construction. These acreages greatly exceed the no net loss (1:1 replacement ratio) requirement for Alternative 1B (552 acres). Therefore, there would be an overall beneficial effect on potential jurisdictional wetlands and other waters of the United States from BDCP implementation.

**CEQA Conclusion:** The permanent and temporary loss of potential jurisdictional wetlands as a result of constructing Alternative 1B water conveyance facilities would be a substantial effect if not compensated for by wetland protection and/or restoration. This loss would represent either temporary or permanent removal of federally protected wetlands or other waters of the United States as defined by Section 404 of the CWA. However, Alternative 1B includes conservation
measures (CM4 and CM10) that would restore and protect large acreages of both tidal and nontidal
wetlands and open water. Through the course of the BDCP restoration program, this alternative
would result in restoration of 65,000 acres of tidal and 1,200 acres of nontidal wetlands and open
water. Impacts on wetlands from CM1 construction would occur in the first 10 years after BDCP
approval. Approximately 19,550 acres of this wetland restoration would occur during this time
period, thereby offsetting the impacts of CM1 construction. These acreages greatly exceed the no net
loss (1:1 replacement ratio) requirement for Alternative 1B (552 acres). Therefore, there would be a
beneficial impact on potential jurisdictional wetlands and other waters of the United States from
BDCP implementation.

**Impact BIO-177: Effects of Implementing Other Conservation Measures (CM2–CM10) on
Wetlands and Other Waters of the United States**

The habitat protection and restoration activities associated with Alternative 1B’s other conservation
measures (CM2–CM10) would alter the acreages and functions and values of wetlands and Waters of
the US in the study area over the course of BDCP conservation action implementation. Because these
conservation measures have not been defined to the level of site-specific footprints, it is not possible
to delineate and quantify these effects in detail. Several of the conservation measures (CM2, CM4
and CM5) have been described with theoretical footprints for purposes of the effects analysis
contained in Chapter 5 of the BDCP. These theoretical footprints have been used to predict the acres
of natural communities that would be affected through loss or conversion, which gives some
indication of jurisdictional wetland effects. Any CM2–CM10 effects ascribed to tidal perennial
aquatic, tidal brackish emergent, tidal freshwater emergent, other natural seasonal, nontidal
freshwater perennial emergent, and nontidal perennial aquatic wetlands natural communities are
likely to also be effects on wetlands and other waters of the United States. Effects ascribed to other
natural communities and land cover types with small jurisdictional wetland components
(valley/foothill riparian, alkali seasonal wetland complex, vernal pool complex, managed wetland,
grassland and cultivated land) are not easily converted to effects on wetlands and other Waters of
the US by the use of theoretical footprints. Because of this lack of detail, a programmatic assessment
is provided for these other conservation measures.

**NEPA Effects:** The conversion of existing wetland natural communities to other types of wetland
natural communities through implementation of CM2–CM10 for Alternative 1B would be in the
range of 5,500 to 6,000 acres, assuming that 100 percent of the predominantly wetland natural
communities listed in Table 12-1B-69 and that 10 percent of all of the non-wetland natural
communities listed in that table would qualify as wetlands or other waters of the United States
under the CWA. Most of these wetlands would be converted to tidal and nontidal wetlands and open
water through implementation of CM4, and CM10. The wetlands and open water created by these
two restoration actions would be approximately 66,200 acres, far exceeding what is required under
the no net loss policy used by the USACE in considering Section 404 permits, even if one were to
assume that all conversions represented a functional wetland loss. Therefore, there would be a
beneficial effect on potential jurisdictional wetlands and other waters of the United States from
implementing CM2–CM10.

**CEQA Conclusion:** The permanent and temporary loss of potential jurisdictional wetlands as a result
of implementing the other conservation measures (CM2–CM10) of Alternative 1B would be a
significant adverse impact if not compensated for by wetland protection and/or restoration. This
loss would represent a removal of federally protected wetlands or other waters of the United States
as defined by Section 404 of the CWA. However, Alternative 1B includes conservation measures
Alternative 1B
Terrestrial Biological Resources

(CM4 and CM10) that would restore large acreages of both tidal and nontidal wetlands and open water in the study area. Over the life of the BDCP restoration program, this alternative would result in restoration of 66,200 acres of tidal and nontidal wetlands and open water, of which 19,550 acres would be restored in the first 10 years. These acreages greatly exceed the no net loss (1:1 replacement ratio) requirement for Alternative 1B (5,500–6,000 acres). Therefore, there would be a beneficial impact on potential jurisdictional wetlands and other waters of the United States from implementing CM2–CM10.

Shorebirds and Waterfowl

Managed wetlands, tidal natural communities, and cultivated lands (including grain and hay crops, pasture, field crops, rice, and idle lands) provide freshwater nesting, feeding, and resting habitat for a large number of Pacific flyway waterfowl and shorebirds. The primary effects of concern for shorebirds and waterfowl are related to the conversion of managed wetland and cultivated lands to tidal marsh associated with habitat restoration. Ducks Unlimited (2013) conducted an analysis to determine the effects of BDCP conservation measures on waterfowl, as well as to determine whether BDCP actions would impede attainment of the goals established by the Central Valley Joint Venture (CVJV) Implementation Plan for the Delta, Yolo, and Suisun Marsh drainage basins. The CVJV efforts are guided by its 2006 Implementation Plan, which is founded on the principles of strategic habitat conservation (Central Valley Joint Venture 2006). Those principles emphasize the establishment of population abundance objectives and the use of species-habitat models to link population objectives to habitat needs. The CVJV has used species-habitat models to translate bird abundance objectives into habitat objectives, while explicitly identifying the biological assumptions that underpin these models and the data used to populate them. As a result, the CVJV’s biological planning provides a framework for evaluating the effects of the BDCP on waterfowl.

The Ducks Unlimited waterfowl analysis focused primarily on dabbling ducks. Less than 5% of all geese in the Central Valley occur in the Yolo, Delta, and Suisun Marsh drainage basins. Moreover, geese in the Central Valley rely mostly on agricultural habitats to meet their food energy needs. The BDCP’s effect on agricultural habitats is limited to the Delta Basin where about 2500 acres of corn now available to geese would be converted to other habitats (Ducks Unlimited 2013: Table 5). Food supplies for geese would still be well in excess of demand even with the loss of these agricultural habitats (Central Valley Joint Venture 2006, Ducks Unlimited 2013). The duck population objectives used in the analysis were taken directly from the CVJV Plan. Dabbling duck species make up 92% of this objective, while diving duck species make up the remaining 8%. Thus, the results were mostly driven by dabbling duck needs and largely interpreted in the context of dabbling duck foraging ecology. The 55,000 acres of Tidal Natural Communities Restoration (CM4) would be expected to benefit diving ducks by providing deep water foraging habitat. Refer to the Ducks Unlimited Report (Ducks Unlimited 2013) for details of the analysis and methods with respect to the TRUMET model used to quantify effects on food biomass and food quality.

An analysis was conducted to determine the effects of the BDCP covered activities on wintering and breeding shorebird habitat (ICF International 2013). This analysis evaluated the relative increase and decrease in natural communities known to provide important foraging, roosting, and breeding habitat. Similar to the waterfowl analysis, the results were broken up into the three Central Valley Joint Venture Basins that overlap with the BDCP study area: Yolo, Delta, and Suisun. Natural community losses and gains were then translated into species-specific outcomes, comparing the relative habitat value of each BDCP natural community for each Central Valley shorebird species (Table 1, ICF International 2013). The shorebird species ranking system displayed in Table 1 (ICF...
International 2013) was modified from a table in Stralberg et. al (2010). The table was created using survey data and experts’ species-specific habitat rankings. The survey data included fall, winter, and spring density data. This resulted in an overall, cross-season representation of habitat requirements.

**Impact BIO-178: Loss or Conversion of Habitat for Waterfowl and Shorebirds as a Result of Water Conveyance Facilities Construction**

Development of the water conveyance facilities (CM1) would result in the permanent removal of approximately 6 acres of managed wetland, 8 acres of tidal wetlands, 24 acres of nontidal wetlands, and 4,091 acres of suitable cultivated lands (including grain and hay crops, pasture, field crops, rice, and idle lands). In addition, 18 acres of managed wetland, 11 acres of tidal wetlands, 11 acres of nontidal wetlands and 7,470 acres of suitable cultivated lands would be temporarily impacted.

These losses of habitat would occur within the first 10 years of Alternative 1B implementation in the Delta Basin. The BDCP has committed to the near-term protection of 15,400 acres of non-rice cultivated lands, 200 acres of rice, and 700 acres of rice or “rice equivalent” natural communities including nontidal wetlands in the near-term. In addition, 4,100 acres of managed wetlands would be created, protected, and enhanced, 8,850 acres of freshwater tidal wetlands would be restored, and 2,000 acres of tidal brackish emergent wetland would be restored (Table 3-4, Chapter 3). Construction activities could have an adverse effect on nesting shorebirds or waterfowl if they were present in or adjacent to work areas and could result in destruction of nests or disturbance of nesting and foraging behaviors. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on nesting birds.

**NEPA Effects:** Habitat loss from construction of the Alternative 1B water conveyance facilities would not result in an adverse effect on shorebirds and waterfowl because of the acres of natural communities and cultivated lands that would be restored and protected in the near-term timeframe. If waterfowl were present in or adjacent to work areas, construction activities could result in destruction or nests or disturbance of nesting and foraging behaviors, which would be an adverse effect on nesting shorebirds and waterfowl. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on nesting birds.

**CEQA Conclusion:** Habitat loss from construction of the Alternative 1B water conveyance facilities would have a less-than-significant impact on shorebirds and waterfowl because of the acres of natural communities and cultivated lands that would be restored and protected in the near-term timeframe. If waterfowl were present in or adjacent to work areas, construction activities could result in destruction of nests or disturbance of nesting and foraging behaviors, which would be a significant impact. Implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce this impact on nesting birds to a less-than-significant level.

**Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds**

See Mitigation Measure BIO-75 under Impact BIO-75.
Impact BIO-179: Loss or Conversion of Habitat for Wintering Waterfowl as a Result of Implementation of Conservation Components

Suisun Marsh: Managed seasonal wetlands in Suisun Marsh would be reduced by an estimated 8,818 acres as a result of Alternative 1B. This would represent a 25% decrease in managed seasonal wetlands compared with long-term conditions without Alternative 1B (Ducks Unlimited 2013, Table 5). There is considerable uncertainty about the biomass and nutritional quality of waterfowl foods produced in the Suisun’s managed wetlands, which makes it difficult to identify the amount of mitigation needed. To address this uncertainty, three levels of food biomass and three levels of nutritional quality were modeled for these existing habitats (Ducks Unlimited 2013, Table 7). Three mitigation scenarios were based on these energetic assumptions of biomass and food quality were then run to determine a minimum acreage of managed seasonal wetlands to be protected and enhanced to compensate for the loss of productivity from habitat conversion to tidal wetlands.

- Scenario 1) Assume that existing managed seasonal wetlands provide low food biomass and low food quality. Under this assumption, the managed seasonal wetlands in Suisun produce 50% of the seed biomass of seasonal wetlands elsewhere in the Central Valley, and these seeds have 60% of the metabolizable energy of seeds produced outside of Suisun. Given the assumption that managed seasonal wetlands in Suisun could be enhanced to provide high food biomass and high food quality (equal to wetlands in the Central Valley), 5,000 acres of managed wetlands protected and managed for high biomass and high food quality would mitigate the conversion of 8,857 acres of managed seasonal wetland to tidal marsh.

- Scenario 2) Assume that the managed seasonal wetlands lost provide medium food biomass and medium food quality. Under this assumption, the managed seasonal wetlands in Suisun produce 75% of the seed biomass of seasonal wetlands elsewhere in the Central Valley, and these seeds have 80% of the metabolizable energy of seeds produced outside of Suisun. Given the assumption that managed seasonal wetlands in Suisun could be enhanced to provide high food biomass and high food quality (equal to wetlands in the Central Valley), 13,300 acres of managed wetlands protected and managed for high biomass and high food quality would mitigate the conversion of 8,857 acres of managed seasonal wetland to tidal marsh.

- Scenario 3) Assume that existing managed seasonal wetlands provide low food biomass and low food quality. Given the assumption that managed seasonal wetlands in Suisun could only be enhanced to provide medium food biomass and medium food quality (produce 75% of the seed biomass of seasonal wetlands elsewhere in the Central Valley, and these seeds have 80% of the metabolizable energy of seeds produced outside of Suisun), 8,800 acres of managed wetlands protected and managed for medium biomass and medium food quality would mitigate the conversion of 8,857 acres of managed seasonal wetland to tidal marsh.

The BDCP has committed to protecting and enhancing a minimum of 5,000 acres of managed seasonal wetlands in Suisun to compensate for the loss of productivity from habitat conversion to tidal marsh. This minimum commitment of 5000 acres would mitigate the reduced productivity from conversion of managed seasonal wetlands under the assumptions that 1) existing managed seasonal wetlands on average in Suisun provide low biomass and low-quality food to wintering waterfowl and 2) protected seasonal wetlands can be managed to produce high biomass and high food quality. However, the food biomass and productivity in Suisun Marsh would need to be quantified in order to determine if the 5,000 acres was sufficient to avoid an adverse effect on wintering waterfowl in the Suisun Marsh, or if additional mitigation would be needed. Mitigation
Measure BIO-179a, *Conduct Food Studies and Monitoring for Wintering Waterfowl in Suisun Marsh*, would be available to address this adverse effect.

**Yolo and Delta Basins:** The replacement of 1,400 acres of managed seasonal wetland with 19,000 acres of palustrine tidal wetlands in the Delta Watershed, and the replacement of 600 acres of managed seasonal wetlands with 2,000 acres of palustrine tidal wetlands in the Yolo Watershed would not be expected to have an adverse effect on food productivity, under the assumption that these wetlands would provide adequate food sources. However, a monitoring component and a food study in these tidal habitats would be necessary order to demonstrate that there is a less-than-significant loss of food value in these habitats for wintering waterfowl. If it is determined from monitoring, that there is in fact a significant loss in food productivity from habitat conversion to tidal wetlands, the protection and enhancement of managed wetlands in these watersheds would be required to mitigate the change in food biomass and quality. Mitigation Measure BIO-179b, *Conduct Food Studies and Monitoring to Demonstrate Food Quality of Palustrine Tidal Wetlands in the Yolo and Delta Basins*, would be available to address this uncertainty.

**NEPA Effects:** There is considerable uncertainty about the biomass and nutritional quality of waterfowl foods produced in Suisun Marsh’s managed wetlands, which makes it difficult to identify the level of effect that Alternative 1B habitat loss or conversion would have. The BDCP has committed to protecting and enhancing a minimum of 6,600 acres of managed seasonal wetlands in Suisun Marsh to compensate for the loss of productivity resulting from habitat conversion to tidal marsh. Of this 6,600 acres, at least 5,000 acres would be managed to benefit wintering waterfowl. This minimum commitment of 5,000 acres for wintering waterfowl would mitigate the reduced productivity from conversion of managed seasonal wetlands under the assumptions that 1) existing managed seasonal wetlands on average in Suisun Marsh provide low biomass and low-quality food to wintering waterfowl and 2) protected seasonal wetlands can be managed to produce high biomass and high-quality food. However, the food biomass and productivity in Suisun Marsh would need to be quantified to determine if the 5,000 acres would be sufficient for Alternative 1B to avoid an adverse effect on wintering waterfowl in the Suisun Marsh. Mitigation Measure BIO-179a, *Conduct Food Studies and Monitoring for Wintering Waterfowl in Suisun Marsh*, would be available to address this adverse effect.

The replacement of 1,400 acres of managed seasonal wetlands with 19,000 acres of palustrine tidal wetlands in the Delta Watershed, and the replacement of 600 acres of managed seasonal wetlands with 2,000 acres of palustrine tidal wetlands in the Yolo watershed would not be expected to alter food productivity for wintering waterfowl. However, the conclusion that these wetlands would provide adequate food sources is entirely dependent on assumptions about food production in palustrine tidal habitats. Mitigation Measure BIO-179b, *Conduct Food Studies and Monitoring to Demonstrate Food Quality of Palustrine Tidal Wetlands in the Yolo and Delta Basins*, would be available to address this uncertainty and avoid an adverse effect on wintering waterfowl.

**CEQA Conclusion:** There is considerable uncertainty about the biomass and nutritional quality of waterfowl foods produced in Suisun Marsh’s managed wetlands, which makes it difficult to identify the level of impact that Alternative 1B habitat loss or conversion would have. The BDCP has committed to protecting and enhancing a minimum of 6,600 acres of managed seasonal wetlands in Suisun Marsh to compensate for the loss of productivity resulting from habitat conversion to tidal marsh. Of this 6,600 acres, at least 5,000 acres would be managed to benefit wintering waterfowl. This minimum commitment of 5,000 acres for wintering waterfowl would mitigate the reduced productivity resulting from conversion of managed seasonal wetlands under the assumptions that
1) existing managed seasonal wetlands on average in Suisun Marsh provide low biomass and low-quality food for wintering waterfowl and 2) protected seasonal wetlands can be managed to produce high biomass and high-quality food. However, the food biomass and productivity in Suisun Marsh would need to be quantified to determine if the 5,000 acres would be sufficient for Alternative 1B to avoid having a significant impact on wintering waterfowl in the Suisun Marsh, or if additional mitigation would be needed. Implementation of Mitigation Measure BIO-179a, Conduct Food Studies and Monitoring for Wintering Waterfowl in Suisun Marsh, would address this potential significant impact.

The replacement of 1,400 acres of managed seasonal wetland with 19,000 acres of palustrine tidal wetlands in the Delta Watershed, and the replacement of 600 acres of managed seasonal wetlands with 2,000 acres of palustrine tidal wetlands in the Yolo Watershed would not be expected to alter food productivity for wintering waterfowl. However, the conclusion that these tidal wetlands would provide adequate food sources is are entirely dependent on assumptions about food production in palustrine tidal habitats. Studies of food biomass and food quality in palustrine tidal habitats are needed to confirm that no mitigation for wintering waterfowl is required in the Yolo and Delta Basins. Implementation of Mitigation Measure BIO-179b, Conduct Food Studies and Monitoring to Demonstrate Food Quality of Palustrine Tidal Wetlands in the Yolo and Delta Basins, would address this uncertainty and would reduce this impact on wintering waterfowl to a less-than-significant level.

Mitigation Measure BIO-179a: Conduct Food Studies and Monitoring for Wintering Waterfowl in Suisun Marsh

Poorly managed wetlands (considered low biomass and food quality) will be identified and managed by BDCP proponents to improve food quality and biomass. Studies will be required to quantify 1) food production of existing managed wetlands in Suisun Marsh and 2) energetic productivity of brackish and tidal marsh habitats. Protected wetlands will be monitored to measure changes in the energetic productivity of these sites. Based on the food studies and monitoring results, BDCP proponents will determine if the minimum commitment of 5,000 acres is sufficient to meet the goal of 1:1 compensation for loss of wintering waterfowl habitat with the protection and management of managed wetlands in perpetuity. If monitoring demonstrates that additional acreage is needed to meet this goal, additional acreage of protection or creation of managed wetlands and management will be required.

Mitigation Measure BIO-179b: Conduct Food Studies and Monitoring to Demonstrate Food Quality of Palustrine Tidal Wetlands in the Yolo and Delta Basins

In order to address the uncertainty of the impact of loss of managed wetlands in the Yolo and Delta Basins on wintering waterfowl, BDCP proponents will conduct food studies and monitoring to demonstrate the food quality of palustrine tidal habitats in these basins. If studies show that the assumption of no effect was inaccurate, and the food quality goal of 1:1 compensation for wintering waterfowl food value is not met, additional acreage of protection or creation of managed wetland and management will be required.
Impact BIO-180: Loss or Conversion of Habitat for Breeding Waterfowl from Implementation of Conservation Components

Yolo and Delta Basins: Alternative 1B would reduce managed wetlands in the Yolo and Delta basins by 437 acres and 1,155 acres respectively. Under the assumption that 15% of these wetlands are managed as semi-permanent wetlands, Alternative 1B would reduce semipermanent wetlands in the Yolo and Delta drainage basins by 77 acres and 203 acres respectively. While a reduction in these semipermanent habitats would represent a habitat loss for breeding waterfowl, with the restoration of 24,000 acres of palustrine tidal wetlands (Table 3-4, Chapter 3) in the Yolo and Delta basins there would be a less than adverse effect on breeding waterfowl. These palustrine habitats would presumably contain water during the breeding period (i.e., March through July), and would be expected to compensate for the loss of 280 acres of managed semi-permanent wetlands in the Yolo and Delta watersheds attributed to Alternative 1B.

Suisun Marsh: Total managed wetlands in Suisun Marsh would decline from 41,012 acres to 30,640 acres from the conversion of managed seasonal and semi-permanent wetlands to tidal habitats. Some of the remaining seasonal wetlands could be managed as semi-permanent wetlands to offset the loss of breeding habitat, but this could further reduce food supplies available to wintering waterfowl under the assumption that semi-permanent wetlands provide few food resources compared to seasonally managed habitats (Central Valley Joint Venture 2006).

The BDCP includes a commitment to protect and enhance 1,600 acres of permanently flooded managed wetlands in Suisun Marsh to provide habitat for breeding waterfowl. In addition, 5,000 acres of semipermanent wetlands that would be protected and enhanced for wintering and migratory waterfowl (Table 3-4, Chapter 3; Objective MWNC1.1 in BDCP Chapter 3, Conservation Strategy).

Food studies and monitoring would be necessary to determine how increases in tidal marsh and salinity levels would affect the overall reproductive capacity of the marsh. These studies would be needed in order to quantify impacts on breeding waterfowl in Suisun Marsh and to determine not only the number of acres that would compensate for loss of breeding habitat at a ratio of 1:1 for habitat value, but how those acres should be managed. Mitigation Measure BIO-180, Conduct Food and Monitoring Studies of Breeding Waterfowl in Suisun Marsh, would be available to address the uncertainty of this effect.

In addition to providing semipermanent wetlands to breeding waterfowl, the Suisun Marsh contains several key upland areas that have significant nesting value. The largest block of upland habitat in the region is the core area on the Grizzly Island Wildlife Area. This area does not overlap with the hypothetical footprint for CM4 Tidal Natural Communities Restoration. However, this core area includes over 2,000 acres of upland grasslands that have some of the highest duck nesting densities in California (Central Valley Joint Venture 2006). A few small wetland areas are scattered within this core grassland mosaic that provide necessary freshwater brooding habitat. If restoration footprints were changed during the implementation process of BDCP to overlap with this area, the effects on breeding waterfowl would likely be greatly increased.

NEPA Effects: Alternative 1B would reduce managed wetlands in the Yolo and Delta basins by 437 acres and 1,155 acres respectively. Under the assumption that 15% of these wetlands are managed as semi-permanent wetlands, Alternative 1B would reduce semipermanent wetlands in the Yolo and Delta drainage basins by 77 acres and 203 acres, respectively. The reduction in these semipermanent habitats would represent a habitat loss for breeding waterfowl. However, with the
restoration of 24,000 acres of palustrine tidal wetlands in the Yolo and Delta basins, Alternative 1B would not have an adverse effect on breeding waterfowl. These palustrine habitats would presumably contain water during the breeding period (March through July), and would be expected to compensate for the loss of 280 acres of managed semi-permanent wetlands in the Yolo and Delta watersheds attributed to Alternative 1B. Total managed wetlands in Suisun Marsh would decline from 41,012 acres to 30,640 acres with the conversion of managed seasonal and semi-permanent wetlands to tidal habitats. Some of the remaining seasonal wetlands could be managed as semi-permanent wetlands to offset the loss of breeding habitat, but such management could further reduce food supplies available to wintering waterfowl under the assumption that semi-permanent wetlands provide few food resources compared with seasonally managed habitats. The protection and enhancement of 1,600 acres of permanently flooded managed wetlands would provide habitat for breeding waterfowl. However, food studies and monitoring would be necessary to determine how increases in tidal marsh and salinity levels would affect the overall reproductive capacity of the marsh. Therefore, the loss of breeding waterfowl habitat resulting from implementation of Alternative 1B could have an adverse effect. Mitigation Measure BIO-180, Conduct Food and Monitoring Studies of Breeding Waterfowl in Suisun Marsh, would be available to address the uncertainty of model assumptions and the potential adverse effect of habitat conversion on breeding waterfowl in Suisun Marsh.

**CEQA Conclusion:** Alternative 1B would reduce managed wetlands in the Yolo and Delta basins by 437 acres and 1,155 acres respectively. Under the assumption that 15% of these wetlands are managed as semi-permanent wetlands, Alternative 1B would reduce semipermanent wetlands in the Yolo and Delta drainage basins by 77 acres and 203 acres respectively. The reduction in these semi-permanent habitats would represent a habitat loss for breeding waterfowl. However, with the restoration of 24,000 acres of palustrine tidal wetlands in the Yolo and Delta basins, Alternative 1B would have a less-than-significant impact on breeding waterfowl. These palustrine habitats would presumably contain water during the breeding period (March through July), and would be expected to compensate for the loss of 280 acres of managed semi-permanent wetlands in the Yolo and Delta watersheds attributed to Alternative 1B.

Total managed wetlands in Suisun Marsh would decline from 41,012 acres to 30,640 acres with the conversion of managed seasonal and semi-permanent wetlands to tidal habitats. Some of the remaining seasonal wetlands could be managed as semi-permanent wetlands to offset the loss of breeding habitat, but this management could further reduce food supplies available to wintering waterfowl under the assumption that semi-permanent wetlands provide few food resources compared with seasonally managed habitats. The protection and enhancement of 1,600 acres of permanently flooded managed wetlands would provide habitat for breeding waterfowl. However, food studies and monitoring would be necessary to determine how increases in tidal marsh and salinity levels would affect the overall reproductive capacity of the marsh. Therefore, the loss or conversion of habitat from implementation of Alternative 1B could have a significant impact on breeding waterfowl in Suisun Marsh. Implementation of Mitigation Measure BIO-180, Conduct Food and Monitoring Studies of Breeding Waterfowl in Suisun Marsh, would address the uncertainty of model assumptions and reduce the impact to a less-than-significant level.

**Mitigation Measure BIO-180: Conduct Food and Monitoring Studies of Breeding Waterfowl in Suisun Marsh**

To address the uncertainty of the impact of loss of managed wetlands in Suisun Marsh on breeding waterfowl, BDCP proponents will conduct food studies and monitoring to determine
how increases in tidal marsh and salinity levels will affect the overall reproductive capacity of the marsh.

The required studies will examine how increases in tidal marsh and salinity levels will affect the overall reproductive capacity of the Marsh. Reproductive studies will address but will not be limited to the following questions:

- How does the distribution of breeding waterfowl in Suisun Marsh differ in tidal versus managed habitats and across salinity gradients?
- How does waterfowl nest success and nest density vary with respect to tidal versus managed habitats and across salinity gradients?
- What are the patterns of habitat selection and movements by waterfowl broods in relation to tidal vs. managed habitats, and are there impacts on duckling survival?
- What is the current relationship between waterfowl reproductive success and interactions with alternate prey and predators, and how is tidal restoration likely to alter these relationships?

**Impact BIO-181: Loss or Conversion of Habitat for Shorebirds from the Implementation of Conservation Components**

Shorebird use of the study area varies by species and fluctuates both geographically and by habitat type throughout the year. Shallow flooded agricultural fields and wetlands support large numbers of wintering and migrating shorebirds (Shuford et al. 1998), particularly least and western sandpipers, dunlin, greater yellowlegs and long-billed dowitcher. Rice lands of the Sacramento Valley provide important breeding habitat for shorebirds such as American avocet and black-necked stilt (Shuford et al. 2004) and have been designated as a Western Hemisphere Shorebird Reserve Network Site of International Importance (Hickey et al. 2003). Managed wetlands provide suitable foraging and roosting habitat for shorebirds; black-necked stilts, avocets, and yellowlegs use this habitat type almost exclusively. Water depth in all of these habitat types is an important habitat variable as the majority of shorebird species require water depths of approximately 10–20 cm for foraging (Isola et al. 2000, Hickey et al. 2003).

**Managed Wetlands**

**Yolo Basin:** Primarily as a result of CM4 Tidal Natural Communities Restoration within the Yolo Basin, 1,185 acres of managed wetland habitat would be permanently converted; 1,066 acres of which are protected. In addition, 42 acres of managed wetland habitat would be temporarily lost by construction-related activities associated with tidal restoration (CM4) and fisheries enhancement activities (CM2) (Table 2, ICF International 2013). Increased inundation frequency, depth and duration associated with the ongoing operation of a modified Fremont Weir (CM2) could periodically affect managed wetlands ranging from an estimated 643 acres during a notch flow of 1,000 cfs to an estimated 2,055 acres during a notch flow of 4,000 cfs (Table 5.4-2, in BDCP Chapter 5, Effects Analysis) in the Yolo Basin.

**Delta Basin:** Within the Delta Basin, 90 acres of managed wetland habitat would be permanently converted, as a result of tidal restoration (CM4). Thirteen of the 90 acres are protected (Table 3, ICF International 2013). Periodic flooding would not affect this natural community type in Delta Basin.
Suisun Basin: Within the Suisun Basin, 11,532 acres of managed wetland habitat would be permanently converted as a result of tidal restoration (CM4); 10,354 of which are protected. (Table 4, ICF International 2013). Periodic flooding would not affect this natural community type in Suisun Basin.

According to Stralberg et al. 2010, the following species of shorebirds had a rank 1 designation for managed wetland habitat suitability (Table 1, ICF International International 2013): black-necked stilt (Himantopus mexicanus), greater yellowlegs (Tringa melanoleuca), and long-billed dowitcher (Limnodromus scolopaceus). Dunlin (Calidris alpine), least sandpiper (Calidris minutilla), semipalmated plover (Charadrius semipalmatus), and western sandpiper (Calidris mauri), had a rank 2 for managed wetland habitat suitability. Black-bellied plover (Pluvialis squatarola) and whimbrel (Numenius phaeopus) both had rank 3 for managed wetland habitat suitability.

Managed wetlands would decrease in overall extent by 20% (Table 5, ICF International International 2013). Most of this loss would occur in Suisun with some additional acreage loss in the Yolo Basin. The loss of managed wetland habitat for covered species and waterfowl would be compensated for with 8,200 acres remaining managed wetland protection in Suisun Marsh. Of these 8,200 acres, the 5,000 acres of seasonal wetland protected, enhanced, and managed to provide overwintering waterfowl foraging habitat would be the habitat type most likely to benefit overwintering shorebirds. However, the 1,600 acres of semi-permanent and permanent managed wetlands for breeding waterfowl and 1,500 acres of managed wetlands for salt marsh harvest mouse would also be expected to have some benefit to wintering and breeding shorebirds.

Cultivated Lands

Yolo Basin: Primarily as a result of tidal restoration (CM4) and Fisheries Enhancement activities (CM2) within the Yolo Basin, 8,309 acres of cultivated lands would be permanently converted; 1,272 acres of which are protected. Also within the Yolo Basin, increased inundation frequency, depth and duration associated with the ongoing operation of a modified Fremont Weir (CM2) could affect an estimated 3,219 acres of cultivated lands during a notch flow of 1,000 cfs to an estimated 5,512 acres during a notch flow of 6,000 cfs (Table 5.4-2, in BDCP Chapter 5, Effects Analysis).

Delta Basin: Within the Delta Basin, as a result of tidal restoration (CM4) and floodplain restoration (CM5), 25,633 acres of cultivated lands would be permanently converted. There would also be an additional 112 acres lost temporarily due to CM5 activities. Of the total permanently converted lands, 3,925 acres are protected (Table 3, ICF International 2013). Seasonal flooding (CM5) on the restored floodplain would periodically affect 738 acres of cultivated lands in Delta.

According to Stralberg et al. 2010, the following species of shorebirds had a rank 1 designation for cultivated lands habitat suitability (Table 1, ICF International 2013): killdeer (Charadrius vociferous), long-billed curlew, and whimbrel within pasture habitat and sandhill crane was ranked 1 for grain and hay crops. Long-billed dowitcher and killdeer both had a rank 2 for idle crop habitat suitability and black-bellied plover was ranked 2 for pasture habitat. Red-necked phalarope (Phalaropus lobatus) and Wilson’s phalarope (Phalaropus tricolor) were both ranked 2 for grain and hay crops. Long-billed dowitcher, dunlin, least sandpiper, and long-billed curlew were all ranked 3 for rice habitat suitability and killdeer was ranked 3 for field crop habitat suitability.

Cultivated land loss would occur in all three basins, but the majority of acreage loss would occur in the Delta basin. Pasture crop types would decrease in overall extent by 15% over baseline (Table 5, ICF International 2013), but would increase in protection by 135%. More than half of all cultivated
lands within the 48,000-acre BDCP cultivated lands reserve would be in pasture production
(primarily alfalfa) and enhanced and managed to benefit Swainson’s hawk. Idle crop types are not
identified as a specific conservation target in the BDCP, are expected to occur within the reserve and
are recognized in the BDCP as having "moderate" foraging habitat value for Swainson’s hawk, white-
tailed kite, and greater sandhill crane.

Grain and hay crop would be expected to decrease by 13% (Table 5, ICF International 2013) while
protection, enhancement and management would be expected to increase by 28% (Table 6, ICF
International 2013). These crop types would be managed for a tricolored blackbirds, Swainson’s
hawk, white-tailed kite, greater sandhill crane, and burrowing owls.

Rice would decrease in overall extent by 2% (Table 5, ICF International 2013) but increase in total
protection by 57%. Rice lands would be protected, enhanced, and managed for the benefit for giant
garter snake.

Tidal Wetlands

Yolo Basin: As a result of tidal restoration (CM4) and Fisheries Enhancement activities (CM2)
within the Yolo Basin, 194 acres of tidal wetland habitat would be permanently converted; 180 acres
of which are protected. In addition, 12 acres of tidal wetland habitat would be temporarily lost by
construction-related activities associated with fisheries enhancement activities (CM2) (Table 2, ICF
International 2013). Periodic flooding in Yolo Bypass would affect 3,957 acres of tidal wetlands in
Yolo Basin.

Delta Basin: Within the Delta Basin, 54 acres of tidal wetlands would be permanently converted as
a result of tidal restoration (CM4) (Table 3, ICF International 2013). Of the total permanently
converted lands, 26 acres are protected. Periodic flooding in Yolo Bypass would affect 26 acres of
tidal wetlands in Delta Basin.

Suisun Basin: Within the Suisun Basin, 219 acres of tidal wetland habitat would be permanently
converted as a result of tidal restoration (CM4); 215 of which are protected. (Table 4, ICF
International 2013). Periodic flooding would not affect this natural community type in Suisun Basin.

According to Stralberg et al. 2010, the following species of shorebirds had a rank 1 designation for
tidal mudflat habitat suitability (Table 6, ICF International 2013): black-bellied plover, dunlin, least
sandpiper, marbled godwit (Limosa fedoa), semipalmated plover, short-billed dowitcher
(Limnodromus griseus), western sandpiper, and willet (Tringa semipalma). Long-billed curlew
(Numenius americanus) and whimbrel both had a rank 2 for tidal mudflat habitat suitability.
American avocet (Recurvirostra americana) was ranked 3 for tidal mudflat habitat suitability. For
tidal brackish emergent wetland/tidal freshwater emergent wetland, willet was ranked 2 and long-
billed curlew and whimbrel were both ranked 3 for habitat suitability.

Tidal mudflat habitat would be estimated to increase in extent by 1,780 acres. This extremely large
increase in tidal mudflat habitat would occur almost exclusively in Suisun Marsh as the result of
tidal restoration and the conversion of existing mid- and high-marsh types to low marsh and tidal
mudflats in response to sea level rise. BDCP Appendix 3.B, BDCP Tidal Habitat Evolution Assessment,
details the methods and assumptions modeled to come about this result. Tidal mudflat habitats
would be expected to require management, however, sediment augmentation has been discussed as
an experimental method that could be employed in places like Suisun to combat the loss of intertidal
marshes in the face of sea level rise and reduced sediment supplies.
Tidal emergent wetland habitat would increase in extent by 152% (Table 5, ICF International 2013). Of the 30,000 acres of emergent wetland restoration, 6,000 acres would be in the Suisun Basin and the rest would be distributed between the Yolo and Delta Basins. Enhancement and management on these lands would be likely to be focused on nonnative, invasive species management. Any additional actions in Suisun would be focused on salt marsh harvest mouse, Suisun shrew, California clapper rail, black rail, Suisun thistle, and soft bird's-beak. In freshwater marshes, enhancement and management would be likely to focus on black rail, western pond turtle, and, in some cases, giant garter snake.

**Nontidal Wetlands**

**Yolo Basin:** As a result of tidal restoration (CM4) and Fisheries Enhancement activities (CM2) within the Yolo Basin, 313 acres of nontidal wetland habitat would be permanently converted; 119 acres of which are protected. In addition, 11 acres of nontidal wetland habitat would be temporarily lost by construction-related activities associated with Fisheries Enhancement activities (CM2) (Table 2, ICF International 2013). Periodic flooding in Yolo Bypass associated with ongoing Fremont Weir operation (CM2) would affect 305 acres of nontidal wetlands in Yolo Basin, specifically nontidal perennial aquatic habitat.

**Delta Basin:** Within the Delta Basin, 99 acres of nontidal wetlands would be permanently converted as a result of tidal restoration (CM4) and floodplain restoration (CM5) (Table 3, ICF International 2013). There would also be 8 acres of nontidal perennial aquatic habitat temporarily lost from CM5 activities. Of the total permanently converted lands, 29 acres are protected. Periodic flooding from CM5 would affect 4 acres of nontidal perennial aquatic habitat in Delta Basin.

**Suisun Basin:** Within the Suisun Basin, 1 acre of nontidal wetland habitat, specifically vernal pool complex, would be permanently converted as a result of tidal restoration (CM4); and is not protected. (Table 4, ICF International 2013). Periodic flooding would not affect this natural community type in Suisun Basin.

According to Stralberg et al. 2010, the following species of shorebirds had a rank 1 designation for nontidal wetland habitat suitability (Table 6, ICF International 2013): red-necked phalarope and Wilson’s phalarope for nontidal freshwater perennial emergent wetland and American avocet for alkali seasonal wetland complex. Greater yellowlegs had a rank 2 for vernal pool complex habitat suitability. Red-necked phalarope and western sandpiper were both ranked 3 for alkali seasonal wetland habitat suitability and greater yellowlegs was ranked 3 for nontidal freshwater perennial emergent wetland habitat suitability.

Nontidal freshwater emergent wetland would increase in extent by 88% as a result of BDCP implementation (Table 5, ICF International 2013). These lands would be managed to benefit giant garter snake and located within the Delta Basin (likely in the vicinity of White Slough) and the Yolo Basin (in the Cache Slough area).

Impacts on wetted acres of vernal pool complex and alkali seasonal wetland complex would be avoided and thus loss of this community is not expected. However, up to 10 acres of wetted acre loss could be permitted under the Plan. Protection of vernal pool complex natural community would increase by 13% and by 6% for alkali seasonal wetlands (Table 6, ICF International 2013). Protection of these two community types would enhance and manage habitat for vernal pool crustaceans and alkali-related plant species.
The protection and restoration of natural communities would also include management and enhancement actions under CM11 Natural Communities Enhancement and Management. The following management activities to benefit shorebirds would be considered for implementation under CM11, in areas where they would not conflict with covered species management.

- Managed wetlands:
  
  - Managed wetlands can be potentially manipulated to provide the optimum water depths for foraging shorebirds and islands for nesting (Hickey et al. 2003).
  
  - During fall and spring, stagger the timing and location of draining and flooding to optimize the extent of shallow-water habitat; varying depths within the wetland unit helps to create temporal variation in foraging opportunities. During warm, dry springs when wetland units dry quickly, wetland units can be re-supplied with water to extend habitat availability for shorebirds.
  
  - Provide open, shallow water habitat adjacent to minimally vegetated, shallowly sloped edges for nesting shorebirds between April and July.
  
  - Provide islands with little to no vegetation to increase the likelihood of shorebird roosting and nesting.
  
  - Create low slopes on islands and levees; gradual angles (10-12:1) are better than steep angles.
  
  - Limit levee maintenance during the nesting season (April through July). However, mowing the center of levees is fine.
  
  - Potentially add material to levees or to islands to encourage nesting for some species.

- Cultivated Lands:
  
  - Maintaining a mosaic of dry and flooded crop types, and varying water depths will promote a diverse community of waterbirds, including shorebirds, during fall migration and winter (Shuford et al. 2013).
  
  - To provide wintering habitat for multiple waterbird guilds, including shorebirds, use a combination of flooding practices that include one-time water application and maintenance flooding while also providing unflooded habitat (Strum et al. in review).
  
  - The post-harvest flooding of winter wheat and potato fields in early fall (July- September) can provide substantial benefits to shorebirds at a time of very limited shallow-water habitat on the landscape (Shuford et al. 2013).
  
  - Stagger the drawdown of flooded rice and other winter-flooded agricultural fields to prolong the availability of flooded habitat (Iglecia et al. 2012). Be aware of soil type because this practice may not be as effective on soils that drain quickly.
  
  - Remove as much stubble as possible in rice and other agricultural fields after harvest to increase the potential shorebird habitat on intentionally flooded or unflooded fields that may passively gather rain water (Iglecia et al. 2012).
  
  - Shallowly flood available agricultural fields during July, August, and September to provide early fall migration habitat for shorebirds. Fields should be free of vegetation prior to flooding, have minimal micro-topography (e.g. no large clods), and should remain flooded.
for up to three week periods (after three weeks, vegetation encroachment reduces habitat value for shorebirds; ICF International 2013).

- Manage levee habitats to have minimal vegetation but do not spray herbicide directly or drive on levees during the nesting season (April- July, Iglecia et al. 2012).
- Maintain a minimum top-width of 30 inches for levees, based on increased avocet use of wider levees (Iglecia et al. 2012).
- When possible, flood fields with nesting habitat (modified levees and islands) in late April to provide nesting habitat for American avocets (Iglecia et al. 2012).
- Finer grained substrate (clods smaller than a fist) in rice and other agricultural fields may be more appealing for nesting shorebirds (Iglecia et al. 2012).
- Islands should be disked along with the rest of the field after harvest to help inhibit vegetation growth (Iglecia et al. 2012).

**NEPA Effects:** Alternative 1B implementation would result in the conversion of managed wetland and cultivated lands to tidal natural communities, including tidal mudflat. The result would be substantial loss of the primary habitat of black-necked stilt, American avocet, greater yellowlegs, and long-billed dowitcher and a gain in the primary habitat of black-bellied plover, dunlin, least sandpiper, marbled godwit, semipalmated plover, short-billed dowitcher, western sandpiper, and willet. While substantial losses of cultivated lands would be incurred, protection, enhancement, and management of the remaining acres would likely have substantial benefits for select species of wintering and breeding shorebirds. This is because impacts on crop types would be distributed across all crop types, while protection would focus primarily on pasture lands, grain and hay, corn, and rice types. While the protection, enhancement, and management of these crop types are being driven by covered species, these management actions would also benefit shorebirds. The protection, enhancement, and management of remaining managed wetlands in Suisun Marsh, in compensation for the loss of substantial acreage, would have some incremental benefits for shorebirds, but would be unlikely to compensate for the overall loss. However, with the protection and restoration of acres in the Delta and Yolo watersheds, in addition to the implementation of the management actions outlined in **CM11 Natural Communities Enhancement and Management**, habitat conversion would not be expected to result in an adverse effect on shorebird populations in the study area.

**CEQA Conclusion:** Alternative 1B implementation would result in the conversion of managed wetland and cultivated lands to tidal natural communities, including tidal mudflat. The result would be significant loss of the primary habitat of black-necked stilt, American avocet, greater yellowlegs, and long-billed dowitcher and a gain in the primary habitat of black-bellied plover, dunlin, least sandpiper, marbled godwit, semipalmated plover, short-billed dowitcher, western sandpiper, and willet. While significant losses of cultivated lands would be incurred, protection, enhancement, and management of the remaining acres would likely have substantial benefits for select species of wintering and breeding shorebirds. This is because impacts on crop types would be distributed across all crop types, while protection would focus primarily on pasture lands, grain and hay, corn, and rice types. While the protection, enhancement, and management of these types are being driven by covered species, these management actions would also benefit shorebirds. The protection, enhancement, and management of remaining managed wetlands in Suisun Marsh, in compensation for substantial acreage loss, would have some incremental benefits for shorebirds, but would be unlikely to compensate for the overall loss. However, with the protection and restoration of acres in
the Delta and Yolo watersheds, in addition to the implementation of the management actions outlined in *CM11 Natural Communities Enhancement and Management*, habitat conversion would be expected to have a less-than-significant impact on shorebird populations in the study area.

**Impact BIO-182: Effects on Shorebirds and Waterfowl Associated with Electrical Transmission Facilities**

New transmission lines installed in the study area would increase the risk for bird-power line strikes, which could result in injury or mortality of shorebirds and waterfowl. The existing network of power lines in the study currently poses a risk for shorebirds and waterfowl in the Delta. New transmission lines would increase this risk and have an adverse effect on shorebird and waterfowl species in the absence of other conservation actions. The implementation of *AMM20 Greater Sandhill Crane* would reduce potential effects through the installation of flight-diverters on new transmission lines, and selected existing transmission lines in the study area.

**NEPA Effects:** New transmission lines would increase the risk for shorebird and waterfowl power line strikes. With the implementation of *AMM20 Greater Sandhill Crane*, the potential effect of the construction of new transmission lines on shorebird and waterfowl would not be adverse.

**CEQA Conclusion:** New transmission lines would increase the risk for shorebird and waterfowl power line strikes. The implementation of *AMM20 Greater Sandhill Crane* would reduce the potential impact of the construction of new transmission lines on shorebirds and waterfowl to a less-than-significant level.

**Impact BIO-183: Indirect Effects of Plan Implementation on Shorebirds and Waterfowl**

**Indirect construction- and operation-related effects:** Noise and visual disturbances associated with construction-related activities could result in temporary disturbances that affect shorebird and waterfowl use of modeled habitat. Indirect effects associated with construction include noise, dust, and visual disturbance caused by grading, filling, contouring, and other ground-disturbing operations. Construction-related noise and visual disturbances could disrupt nesting and foraging behaviors, and reduce the functions of suitable habitat which could result in an adverse effect on these species. Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to minimize adverse effects on active nests. The use of mechanical equipment during water conveyance construction could cause the accidental release of petroleum or other contaminants that could affect shorebirds and waterfowl or their prey in the surrounding habitat. AMM1–AMM7, including *AMM2 Construction Best Management Practices and Monitoring*, would minimize the likelihood of such spills from occurring. The inadvertent discharge of sediment or excessive dust adjacent to shorebirds and waterfowl in the study area could also have a negative effect on these species. AMM1–AMM7 would ensure that measures were in place to prevent runoff from the construction area and the negative effects of dust on wildlife adjacent to work areas.

**Methylmercury Exposure:** Covered activities have the potential to exacerbate bioaccumulation of mercury in avian species, including shorebird and waterfowl species. Marsh (tidal and nontidal) and floodplain restoration have the potential to increase exposure to methylmercury. Mercury is transformed into the more bioavailable form of methylmercury in aquatic systems, especially areas subjected to regular wetting and drying such as tidal marshes and flood plains (Alpers et al. 2008). Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of mercury (see BDCP Chapter 3, *Conservation Strategy*, for details of restoration). Species sensitivity
to methylmercury differs widely and there is a large amount of uncertainty with respect to species-specific effects. Increased methylmercury associated with natural community and floodplain restoration could indirectly affect shorebirds and waterfowl, via uptake in lower tropic levels (as described in BDCP Appendix 5.D, Contaminants).

In addition, the potential mobilization or creation of methylmercury within the Plan Area varies with site-specific conditions and would need to be assessed at the project level. CM12 Methylmercury Management contains provisions for project-specific Mercury Management Plans. Site-specific restoration plans that address the creation and mobilization of mercury, as well as monitoring and adaptive management as described in CM12 would be available to address the uncertainty of methylmercury levels in restored tidal marsh and potential impacts on shorebirds and waterfowl.

**Selenium Exposure:** Selenium is an essential nutrient for avian species and has a beneficial effect in low doses. However, higher concentrations can be toxic (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and can lead to deformities in developing embryos, chicks, and adults, and can also result in embryo mortality (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009). The effect of selenium toxicity differs widely between species and also between age and sex classes within a species. In addition, the effect of selenium on a species can be confounded by interactions with the effects of other contaminants such as mercury (Ackerman and Eagles-Smith 2009).

The primary source of selenium bioaccumulation in birds is through their diet (Ackerman and Eagles-Smith 2009, Ohlendorf and Heinz 2009) and selenium concentration in species differs by the trophic level at which they feed (Ackerman and Eagles-Smith 2009, Stewart et al. 2004). At Kesterson Reservoir in the San Joaquin Valley, selenium concentrations in invertebrates have been found to be two to six times the levels in rooted plants. Furthermore, bivalves sampled in the San Francisco Bay contained much higher selenium levels than crustaceans such as copepods (Stewart et al. 2004). Studies conducted at the Grasslands in Merced County recorded higher selenium levels in black-necked stilts which feed on aquatic invertebrates than in mallards and pintails, which are primarily herbivores (Paveglio and Kilbride 2007). Diving ducks in the San Francisco Bay (which forage on bivalves) have much higher levels of selenium levels than shorebirds that prey on aquatic invertebrates (Ackerman and Eagles-Smith 2009). Therefore, birds that consume prey with high levels of selenium have a higher risk of selenium toxicity.

Selenium toxicity in avian species can result from the mobilization of naturally high concentrations of selenium in soils (Ohlendorf and Heinz 2009) and covered activities have the potential to exacerbate bioaccumulation of selenium in avian species, including shorebird and waterfowl species. Marsh (tidal and nontidal) and floodplain restoration have the potential to mobilize selenium, and therefore increase avian exposure from ingestion of prey items with elevated selenium levels. Thus, BDCP restoration activities that create newly inundated areas could increase bioavailability of selenium (see BDCP Chapter 3, Conservation Strategy, for details of restoration). Changes in selenium concentrations were analyzed in Chapter 8, Water Quality, and it was determined that, relative to Existing Conditions and the No Action Alternative, CM1 would not result in substantial, long-term increases in selenium concentrations in water in the Delta under any alternative. However, it is difficult to determine whether the effects of potential increases in selenium bioavailability associated with restoration-related conservation measures (CM4–CM5) would lead to adverse effects on shorebirds and waterfowl species.
Because of the uncertainty that exists at this programmatic level of review, there could be a substantial effect on shorebirds and waterfowl from increases in selenium associated with restoration activities. This effect would be addressed through the implementation of AMM27 Selenium Management (BDCP Appendix 3.C, Avoidance and Minimization Measures) which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Furthermore, the effectiveness of selenium management to reduce selenium concentrations and/or bioaccumulation would be evaluated separately for each restoration effort as part of design and implementation. This avoidance and minimization measure would be implemented as part of the tidal habitat restoration design schedule.

**NEPA Effects:** Noise and visual disturbances from the construction of water conveyance facilities could reduce shorebird and waterfowl use of modeled habitat adjacent to work areas. Moreover, operation and maintenance of the water conveyance facilities, including the transmission facilities, could result in ongoing but periodic postconstruction disturbances that could affect shorebird and waterfowl use of the surrounding habitat. AMM1–AMM7 would minimize these effects, and Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would be available to address adverse effects on nesting individuals. Tidal habitat restoration could result in increased exposure of shorebirds and waterfowl to selenium. This effect would be addressed through the implementation of AMM27 Selenium Management, which would provide specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of selenium and its bioavailability in tidal habitats. Therefore, the indirect effects associated with noise and visual disturbances, and increased exposure to selenium from Alternative 1B implementation would not have an adverse effect on shorebirds and waterfowl. Tidal habitat restoration is unlikely to have an adverse effect on shorebirds and waterfowl through increased exposure to methylmercury, as these species currently nest and forage in tidal marshes with elevated methylmercury levels. However, it is unknown what concentrations of methylmercury are harmful to species of waterfowl and shorebirds, and the potential for increased exposure would vary substantially within the study area. Site-specific restoration plans in addition to monitoring and adaptive management, described in CM12 *Methylmercury Management*, would address the uncertainty of methylmercury levels in restored tidal marsh. Once site-specific sampling and other information is developed, the site-specific planning phase of marsh restoration would be the appropriate place to assess the potential risk of shorebird and waterfowl exposure to methylmercury.

**CEQA Conclusion:** Noise, potential hazardous spills, and increased dust and sedimentation as a result of water conveyance facilities construction and operation and maintenance would have a significant impact on shorebirds and waterfowl. AMM1–AMM7 would minimize these impacts, and implementation of Mitigation Measure BIO-75, *Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds*, would reduce the impacts to a less-than-significant level. Tidal habitat restoration is unlikely to have a significant impact on shorebirds and waterfowl species through increased exposure to methylmercury, as these species currently nest and forage in tidal marshes with elevated methylmercury levels. However, it is unknown what concentrations of methylmercury are harmful to species of waterfowl and shorebirds. Site-specific restoration plans that address the creation and mobilization of mercury, as well as the monitoring and adaptive management described in CM12, would be the appropriate place to assess the potential risk of shorebird and waterfowl exposure to methylmercury in the study area. Tidal habitat restoration could result in increased exposure of shorebirds and waterfowl to selenium. This effect would be
addressed through the implementation of *AMM27 Selenium Management*, which would provide
specific tidal habitat restoration design elements to reduce the potential for bioaccumulation of
selenium and its bioavailability in tidal habitats. Therefore, the indirect effects of Alternative 1B
implementation would have a less-than-significant impact on shorebirds and waterfowl.

**Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds**

See Mitigation Measure BIO-75 under Impact BIO-75.

**Common Wildlife and Plants**

Common wildlife and plants are widespread, often abundant, species that are not covered under
laws or regulations that address conservation or protection of individual species. Examples of
common wildlife and plants occurring in the study area are provided within the discussion for each
natural community type in Section 12.1.2.2, *Special-Status and Other Natural Communities*. Impacts
on common wildlife and plants would occur through the same mechanisms discussed for natural
communities and special-status wildlife and plants for each alternative.

**Impact BIO-184: Effects on Habitat and Populations of Common Wildlife and Plants**

Effects on habitat of common wildlife and plants, including habitat removal and conversion, are
discussed in the analysis of Alternative 1B effects on natural communities (Impacts BIO-1 through
BIO-31). In general, effects on habitat of common wildlife and plants would not be adverse. Through
the course of implementing the Plan over a 50-year time period, several natural communities and
land cover types would be reduced in size, primarily from restoration of other natural communities.
Grassland, managed wetland and cultivated land would be reduced in acreage, so the common
species that occupy these habitats would be affected. However, the losses in acreage and value of
these habitats would be offset by protection, restoration, enhancement and management actions
contained in the BDCP, including *CM3 Natural Communities Protection and Restoration, CM4 Tidal Natural Communities Restoration, CM5 Seasonally Inundated Floodplain Restoration, CM6 Channel Margin Enhancement, CM7 Riparian Natural Community Restoration, CM8 Grassland Natural Community Restoration, CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration, CM10 Nontidal Marsh Restoration, and CM11 Natural Communities Enhancement and Management*. In
addition, the AMMs contained in Appendix 3.C of the BDCP would be in place to reduce or eliminate
the potential to adversely affect both special-status and common wildlife and plants.

Direct effects on common wildlife and plants from constructing water conveyance facilities and
implementing BDCP conservation measures would include construction or inundation-related
disturbances that result in injury or mortality of wildlife or plants and the immediate displacement
of wildlife. Indirect effects include project-related disturbances to nearby wildlife and plants during
construction (e.g., disruption of breeding and foraging behaviors from noise and human activity,
habitat degradation from fugitive dust and runoff) and effects occurring later in time (e.g., collisions
of birds with transmission lines, habitat fragmentation, vegetation management). Indirect effects
could result both from construction and from operations and maintenance (e.g., ground
disturbances could result in the spread and establishment of invasive plants or noxious weeds).

**NEPA Effects**: The direct and indirect effects associated with constructing water conveyance
facilities and restoring tidal and other habitats as part of implementing Alternative 1B would not be adverse because the conservation measures and AMMs also expand and protect natural
Terrestrial Biological Resources

Alternative 1B

communities, avoid or minimize effects on special-status species, prevent the introduction and
spread of invasive species, and enhance natural communities. These actions would result in avoiding
and minimizing effects on common wildlife and plants as well.

CEQA Conclusion: Construction and operation of the water conveyance facilities and habitat
restoration activities would have impacts on common wildlife and plants in the study area through
habitat loss and through direct or indirect loss or injury of individuals. The loss of habitat would not
be substantial, because habitat restoration would increase the amount and extent of habitat
available for use by most common wildlife and plant species. Conservation measures to avoid or
minimize effects on special-status species, to prevent the introduction and spread of invasive
species, and to enhance natural communities also would result in avoiding and minimizing effects on
common wildlife and plants. Consequently, implementation of the BDCP is not expected to cause any
populations of common wildlife or plants to drop below self-sustaining levels, and this impact would
be less than significant. No mitigation would be required.

Wildlife Corridors

ECAs are lands likely to be important to wildlife movement between large, mostly natural areas at
the state wide level. The ECAs form a functional network of wildlands that are considered important
to the continued support of California’s diverse natural communities. Four general areas were
identified within the study area that contain ECAs (Figure 12-2). The BDCP also identified important
landscape linkages in the Plan Area to guide reserve design, which can also be seen on Figure 12-2.

Impact BIO-185: Effect of BDCP Conservation Measures on Wildlife Corridors

Alternative 1B water conveyance facilities would cross one of the ECAs identified during the
analysis, the Stone Lake-Yolo Bypass ECA. The conveyance facilities would also cross four landscape
linkages identified in the BDCP, the San Joaquin River linkage (#5 in Figure 12-2), the Middle River
linkage (#6 in Figure 12-2), the Cosumnes to Stone Lakes linkage (#10 in Figure 12-2), and the White
Slough to Stone Lakes linkage (#11 in Figure 12-2). Though the conveyance facilities shown on
Figure 12-2 overlap with the line representing the Sacramento River linkage (#9 in Figure 12-2) this
line generally represents the course of the Sacramento River and is intended to address the needs of
aquatic species and will thus not be addressed in this chapter.

The construction of Intakes 1 2, 3, and 4, associated borrow and spoil areas, and the canal from east
of Clarksburg to just north of Walnut Grove would occur within the Stone Lake-Yolo Bypass ECA.
These activities would result in the permanent loss of narrow strips of riparian vegetation along the
Sacramento River and the permanent and temporary loss of grasslands and agricultural lands. These
loses would not substantially increase impediments to movement of wildlife that could move from
Stone Lakes to Yolo Bypass because the Sacramento River and Sacramento Deep Water Shipping
Channel already create a barrier to dispersal for nonavian species and the loss of the narrow strips
of riparian vegetation and agricultural lands would generally not impede the movement of bird
species between these areas. However, the construction of the canal and the intakes would create a
substantial barrier to the north-south movement of nonavian terrestrial species in the area between
the Sacramento River and the Southern Pacific Dredger Cut west of Stone Lakes, as well as the east-
west movement between Stone Lakes and the east bank of the Sacramento River. There are records
of Swainson’s hawk, western pond turtle, and American badger that would be affected by
construction of the canal (California Department of Fish and Wildlife 2013). Though there would be
losses in Swainson’s hawk foraging habitat and potential nesting habitat in these areas, these loses
would not substantially impede the movements of Swainson’s hawks in the area. The loss in habitat is addressed in the Swainson’s hawk effects analysis.

The addition of new permanent transmission lines within the Stone Lake-Yolo Bypass ECA could adversely affect birds during periods of low visibility. Sandhill cranes that are known to roost at Stones Lakes could particularly be adversely affected by the addition of the north-south running transmission line to the west of Stone Lakes.

The canal and a borrow and spoils area that occur adjacent to the Casumnes to Stone Lakes linkage, which is identified in the BDCP for reserve planning to benefit greater sandhill crane movement from north to south in the Plan Area, could be in conflict with future reserve planning in this area (see impact discussions for greater and lesser sandhill cranes).

The portion of the canal and associated borrow and spoils area that cross the White Slough to Stone Lakes linkage, which is identified in the BDCP for reserve planning to connect the White Slough population of giant garter snake to habitat in the Stone Lakes area, would conflict with BDCP’s reserve design planning as well limiting connectivity under Existing Conditions by creating a substantial barrier to movement across this landscape.

Alternative 1B would also cross the Middle River and San Joaquin River linkages. These linkages were established to guide riparian restoration and protection along the Middle River and San Joaquin River to improve riparian connectivity for the benefit of riparian brush rabbit, riparian woodrat, least Bell’s vireo, yellow-breasted chat, yellow-billed cuckoo, Swainson’s hawk, and white-tailed kite. Though the canal siphons below both of these river crossings, the adjacent canal, borrow and spoils areas, RTM storage areas, and permanent transmission line would remove existing riparian vegetation at these locations and conflict with the BDCP’s plans for establishing habitat connectivity along these river corridors through restoration and preservation.

Restoration activities would occur in the ECAs within Yolo Bypass (CM2 Yolo Bypass Fisheries Enhancement) and within the Grizzly Island-Lake Marie ECA (CM4 Tidal Natural Communities Restoration). These activities would generally improve the movement of wildlife within and outside of the study area. In addition, the preservation of restored lands (CM3) and the enhancement and management of these areas (CM11) would improve and maintain wildlife corridors within the Plan Area.

**NEPA Effects:** Despite the contributions from restoration and protection activities, Alternative 1B would create substantial barriers to the movement of terrestrial wildlife from the eastern portion of the study area into the central Delta, to the north-south movement of wildlife between the Sacramento River and I-5, and create barriers to safe movement of avian species during periods of low visibility. The Alternative 1B conveyance facilities would result in adverse effects on wildlife corridors.

**CEQA Conclusion:** Alternative 1B water conveyance facilities would create a substantial barrier to the north-south movement of terrestrial species in the area between the Sacramento River and the Southern Pacific Dredger Cut west of Stone Lakes, as well as the east-west movement between Stone Lakes and the east bank of the Sacramento River within the Stone Lakes-Yolo Bypass ECA.

The addition of new permanent transmission lines within the Stone Lake-Yolo Bypass ECA could adversely affect birds during periods of low visibility. Sandhill cranes that are known to roost at Stones Lakes could particularly be adversely affected by the addition of the north-south running transmission line to the west of Stone Lakes.
The canal, associated borrow and spoils areas, RTM storage areas, and permanent transmission lines would conflict with the BDCP’s reserve design planning for greater sandhill crane, giant garter snake, and covered riparian species.

Restoration activities would occur in the ECAs within Yolo Bypass (CM2 Yolo Bypass Fisheries Enhancement) and within the Grizzly Island-Lake Marie ECA (CM4 Tidal Natural Communities Restoration). These activities would generally improve the movement of wildlife within and outside of the study area. In addition, the preservation of restored lands (CM3) and the enhancement and management of these areas (CM11) would improve and maintain wildlife corridors within the study area.

Despite the contributions from restoration and protection activities, Alternative 1B would create a substantial barrier to the movement of terrestrial wildlife from the eastern portion of the Plan Area into the central Delta, to the north-south movement of wildlife between the Sacramento River and I-5, and create barriers to safe movement of avian species during periods of low visibility. The Alternative 1B conveyance facilities would result in significant unavoidable impacts on wildlife corridors. There is no practicable mitigation measure to reduce this impact to a less-than-significant level.

Invasive Plant Species

The invasive plant species that primarily affect each natural community in the study area, which include water hyacinth, perennial pepperweed, giant reed, and Brazilian waterweed, are discussed in Section 12.1.4, Invasive and Noxious Plant Species. Invasive species compete with native species for resources and can alter natural communities by altering fire regimes, hydrology (e.g., sedimentation and erosion), light availability, nutrient cycling, and soil chemistry, but also have the potential to harm human health and the economy by adversely affecting natural ecosystems, water delivery, flood protection systems, recreation, agricultural lands, and developed areas (Randall and Hoshovsky 2000). The construction and restoration activities covered under the BDCP could result in the introduction or spread of invasive plant species by creating temporary ground disturbance that provides opportunities for colonization by invasive plants in the study area.

The primary mechanisms for the introduction of invasive plants as the result of implementation of Alternative 1B are:

- Grading, excavation, grubbing, and placement of fill material.
- Breaching, modification, or removal of existing levees and construction of new levees.
- Modification, demolition, and removal of existing infrastructure (e.g., buildings, roads, fences, electric transmission and gas lines, irrigation infrastructure).
- Maintenance of infrastructure.
- Removal of existing vegetation and planting/seeding of vegetation.
- Maintaining vegetation and vegetation structure (e.g., grazing, mowing, burning, trimming).
- Dredging waterways.

Clearing operations and the movement of vehicles, equipment, and construction materials in the study area would facilitate the introduction and spread of invasive plants by bringing in or moving seeds and other propagules. These effects would result from:
• Spreading chipped vegetative material from clearing operations over topsoil after earthwork operations are complete.
• Importing, distributing, storing, or disposing of fill, borrow, spoil, or dredge material.
• Traffic from construction vehicles (e.g., water and cement trucks) and personal vehicles of construction staff.
• Transport of construction materials and equipment within the study area and to/from the study area.

Table 12-1B-70 lists the acreages of temporary disturbance in each natural community in the study area that would result from implementation of Alternative 1B of the BDCP.

Impact BIO-186: Adverse Effects on Natural Communities Resulting from the Introduction and Spread of Invasive Plant Species

Under Alternative 1B, the BDCP would have adverse effects on natural communities from the introduction and spread of invasive plant species through implementation of CM1–CM10 and CM22 (AMM6). No adverse effects are expected from implementation of CM11–CM21.

• **CM1 Water Facilities and Operations:** Construction of the Alternative 1B water conveyance facilities would result in the temporary disturbance of 13,133 acres that would provide opportunities for colonization by invasive plant species.

• **CM2 Yolo Bypass Fisheries Enhancement:** Construction of the Yolo Bypass fisheries enhancements would result in the temporary disturbance of 758 acres that would provide opportunities for colonization by invasive plant species. Vegetation maintenance activities for the Fremont Weir and Yolo Bypass improvements may include the removal of giant reed; however, the clearing of linear areas to facilitate water flow may also result increased opportunities for invasion. Sediment removal, transportation, and application as a source...
material for restoration or levee projects as part of Fremont Weir and Yolo Bypass maintenance activities could also result in the spread of invasives if the sediment contains viable invasive plant propagules.

- **CM3 Natural Communities Protection and Restoration:** The restoration activities in the natural communities located in the eleven CZs would result in the temporary disturbance of restoration areas that would provide opportunities for colonization by invasive plant species.

- **CM4 Tidal Natural Communities Restoration:** The activities associated with the restoration of tidal perennial aquatic, tidal mudflat, tidal freshwater emergent wetland, and tidal brackish emergent wetland in ROAs would result in the temporary disturbance of tidal areas that would provide opportunities for colonization by invasive plant species. These adverse effects would be reduced by designing restoration projects to minimize the establishment of nonnative submerged aquatic vegetation, and early restoration projects would be monitored to assess the response of nonnative species to restoration designs and local environmental conditions. If indicated by monitoring results, the BDCP Implementation Office would implement invasive plant control measures in restored natural communities to help ensure the establishment of native marsh plain plant species. Additionally, the BDCP Implementation Office would actively remove submerged and floating aquatic vegetation in subtidal portions of tidal natural community restoration sites.

- **CM5 Seasonally Inundated Floodplain Restoration:** Floodplain restoration levee construction would result in the temporary disturbance of 1,285 acres along channels in the north, east, and south Delta (San Joaquin, Old, and Middle Rivers) that would provide opportunities for colonization by invasive plant species.

- **CM6 Channel Margin Enhancement:** The temporary effects of channel margin enhancement were not estimated because specific locations for this activity and their areal extent have not been developed. Channel margin enhancement (Sacramento River between Freeport and Walnut Grove, San Joaquin River between Vernalis and Mossdale, Steamboat and Sutter Sloughs, and salmonid migration channels in the interior Delta) would result in the temporary disturbance of channel areas that would provide opportunities for colonization by invasive plant species.

- **CM7 Riparian Natural Community Restoration:** The restoration of valley/foothill riparian habitat would result in the temporary disturbance of riparian areas that would provide opportunities for colonization by invasive plant species.

- **CM8 Grassland Natural Community Restoration:** The restoration of grassland habitat in CZ 1, CZ 8 and/or CZ 11 would result in the temporary disturbance of degraded grassland or cultivated land that would provide opportunities for colonization by invasive plant species.

- **CM9 Vernal Pool and Alkali Seasonal Wetland Complex Restoration:** The restoration of vernal pool and alkali seasonal wetland complexes in CZ 1, CZ 8, or CZ 11 would result in the temporary disturbance of grassland areas that would provide opportunities for colonization by invasive plant species.

- **CM10 Nontidal Marsh Restoration:** Nontidal marsh restoration, which would take place through conversion of agricultural lands in CZ 2 and CZ 4, would result in the temporary disturbance of fallow agricultural areas that would provide opportunities for colonization by invasive plant species. These adverse effects would be reduced by monitoring the development of marsh vegetation to determine if nonnative vegetation needs to be controlled to facilitate the establishment of native marsh vegetation or if restoration success could be improved with
supplemental plantings of native species. If indicated by monitoring, nonnative vegetation control measures and supplemental plantings would be implemented.

- **CM22 Avoidance and Minimization Measures: AMM6 Disposal and Reuse of Spoils, Reusable Tunnel Material, and Dredged Material** would have adverse effects if spoil, RTM, dredged material, or chipped vegetative materials containing viable invasive plant propagules are used as topsoil in uninfested areas.

The adverse effects that would result from the introduction and spread of invasive plants through colonization of temporarily disturbed areas would be minimized by implementation of CM11, AMM4, AMM10, and AMM11.

**CM11 Natural Communities Enhancement and Management** would reduce these adverse effects by implementing invasive plant control within the BDCP reserve system to reduce competition on native species, thereby improving conditions for covered species, ecosystem function, and native biodiversity. The invasive plant control efforts would target new infestations that are relatively easy to control or the most ecologically damaging nonnative plants for which effective suppression techniques are available. In aquatic and emergent wetland communities, Brazilian waterweed, perennial pepperweed, barbgrass, and rabbits foot grass would be controlled (and tidal mudflats would be maintained). In riparian areas, invasive plant control would focus on reducing or eliminating species such as Himalayan blackberry, giant reed, and perennial pepperweed. In grassland areas, techniques such as grazing and prescribed burning may be used to decrease the cover of invasive plant species.

Implementation of AMM4, AMM10 and AMM11 in CM22 would also reduce the adverse effects that could result from construction activities. The AMMs provide methods to minimize ground disturbance, guidance for developing restoration and monitoring plans for temporary construction effects, and measures to minimize the introduction and spread of invasive plants. AMM4 would include the preparation and implementation of an erosion and sediment control plan that would control erosion and sedimentation and restore soils and vegetation in affected areas. The restoration and monitoring plans for implementation of AMM10 would include methods for stockpiling, storing, and restoring topsoil, revegetating disturbed areas, monitoring and maintenance schedules, adaptive management strategies, reporting requirements, and success criteria. AMM10 would also include planting native species appropriate for the natural community being restored, with the exception of some borrow sites in cultivated lands that would be restored as grasslands.

AMM11 specifies that the BDCP Implementation Office would retain a qualified botanist or weed scientist prior to clearing operations to determine if affected areas contain invasive plants. If areas to be cleared do contain invasive plants, then chipped vegetation material from those areas would not be used for erosion control but would be disposed to minimize the spread of invasive plant propagules (e.g., burning, composting). During construction of the water conveyance facilities and construction activities associated with the other CMs, construction vehicles and construction machinery would be cleaned prior to entering construction sites that are in or adjacent natural communities other than cultivated lands and prior to entering any BDCP restoration sites or conservation lands other than cultivated lands. Vehicles working in or travelling off paved roads through areas with infestations of invasive plant species would be cleaned before travelling to other parts of the Plan Area. Cleaning stations would be established at the perimeter of BDCP covered activities along construction routes as well as at the entrance to reserve system lands. Biological monitoring would include locating and mapping locations of invasive plant species within the
construction areas during the construction phase and the restoration phase. Infestations of invasive plant species would be targeted for control or eradication as part of the restoration and revegetation of temporarily disturbed construction areas.

**NEPA Effects:** The implementation of AMM4, AMM10, AMM11, and CM11 would reduce the potential for the introduction and spread of invasive plants and avoid or minimize the potential effects on natural communities and special-status species; therefore, these effects would not be adverse.

**CEQA Conclusion:** Under Alternative 1B, impacts on natural communities from the introduction or spread of invasive plants as a result of implementing Alternative 1B would not result in the long-term degradation of a sensitive natural community due to substantial alteration of site conditions and would, therefore, be less than significant. No mitigation would be required.

**Compatibility with Plans and Policies**

**Impact BIO-187: Compatibility of the Proposed Water Conveyance Facilities and Other Conservation Measures with Federal, State, or Local Laws, Plans, Policies, or Executive Orders Addressing Terrestrial Biological Resources in the Study Area**

Constructing the water conveyance facilities (CM1) and implementing CM2–CM22 for Alternative 1B have the potential for being incompatible with plans and policies related to managing and protecting terrestrial biological resources of the study area. A number of laws, plans, policies, programs, and executive orders that are relevant to actions in the study area provide guidance for terrestrial biological resource issues as overviewed in Section 12.2, *Regulatory Setting*. This overview of plan and policy compatibility evaluates whether Alternative 1B would be compatible or incompatible with such enactments, rather than whether impacts would be adverse or not adverse, or significant or less than significant. If the incompatibility relates to an applicable plan, policy, or executive order adopted to avoid or mitigate terrestrial biological resource effects, then an incompatibility might be indicative of a related significant or adverse effect under CEQA and NEPA, respectively. Such physical effects of Alternative 1B on terrestrial biological resources are addressed in the discussions of impacts on natural communities and species. The following is a summary of compatibility evaluations related to terrestrial biological resources for laws, plans, policies, and executive orders relevant to the BDCP.

**Federal and State Legislation**

- The federal *Clean Water Act, Endangered Species Act, Fish and Wildlife Coordination Act, Migratory Bird Treaty Act, Rivers and Harbors Act* and *Marine Mammal Protection Act* all contain legal guidance that either directly or indirectly promotes or stipulates the protection and conservation of terrestrial biological resources in the process of undertaking activities that involve federal decision making. The biological goals and objectives contained in the BDCP that provide the major guidance for implementing the various conservation elements of Alternative 1B are all designed to promote the long-term viability of the natural communities, special-status species, and common species that inhabit the Plan Area. While some of the conservation measures of the alternative involve permanent and temporary loss of natural communities and associated habitats during facilities construction and expansion of certain natural communities, the long-term guidance in the Plan would provide for the long-term viability and expansion of the habitats and special-status species populations in the Plan Area. Alternative 1B conservation
actions would be compatible with the policies and directives for terrestrial biological resources contained in these federal laws.

- The California Endangered Species Act, California Native Plant Protection Act, Porter-Cologne Water Quality Control Act, and Natural Communities Conservation Planning Act are state laws that have relevance to the management and protection of terrestrial biological resources in the study area. Each of these laws promotes consideration of wildlife and native vegetation either through comprehensive planning or through regulation of activities that may have an adverse effect on the terrestrial and aquatic natural resources of the state. The BDCP, which is the basis for Alternative 1B, contains biological goals and objectives that have been developed to promote the species protection and natural resource conservation that are directed by these state laws. Alternative 1B conservation actions would be compatible with the policies and directives contained in these laws.

- The Johnston-Baker-Andal-Boatwright Delta Protection Act of 1992 (Delta Protection Act) and the Sacramento-San Joaquin Delta Reform Act, which updated the Delta Protection Act, promote the maintenance and protection of natural resources and the protection of agricultural land uses in the Delta's primary zone through the goals and policies contained in the 2009 updated Land Use and Resources Management Plan (LURMP). While nothing in the LURMP is binding on state agencies that are BDCP proponents, the LURMP does promote restoration and enhancement of habitats for the terrestrial and aquatic species of the Delta on public land. The BDCP biological goals and objectives would be compatible with these LURMP goals (Delta Protection Commission 2010).

- The Suisun Marsh Preservation Act of 1974 was designed to protect the Suisun Marsh for long-term use as wildlife habitat, with a goal of preserving and enhancing the value and diversity of the Marsh's aquatic and wildlife habitats. The BDCP and its plans for protection and restoration of tidal marsh habitats in Suisun Marsh would be compatible with the intent of the Suisun Marsh Preservation Act.

Plans, Programs, and Policies

- The Delta Plan, which was developed by the Delta Stewardship Council in compliance with the 2009 Sacramento-San Joaquin Delta Reform Act, is mandated to achieve two co-equal goals: provide for a more reliable water supply for California and protect, restore, and enhance the Delta ecosystem. The co-equal goals are to be achieved in a manner that protects and enhances the unique cultural, recreational, natural resource, and agricultural values of the Delta as an evolving place. The BDCP is intended to become a component of the Delta Plan. The Delta Stewardship Council will determine whether the BDCP is compatible with the goals and objectives of the Delta Plan prior to its incorporation into the Plan. The compatibility of the BDCP with the Delta Plan is considered in detail in Section 13.2.2.2 of Chapter 13, Land Use.

- California Wetlands Conservation Policy, which was adopted by Executive Order in 1993, promotes a long-term gain in the quantity, value and permanence of wetlands acreages and values in California. The BDCP conservation measures that provide for a significant expansion of wetland acreage and value in the Delta and Suisun Marsh are compatible with the intent of the California Wetlands Conservation Policy.

- The North American Waterfowl Management Plan (NAWMP) and Central Valley Joint Venture (CVJV) strive to maintain and expand wetlands and uplands for waterfowl and shorebirds in the major basins of California's Central Valley. The NAWMP is a management plan jointly approved
by the United States and Canada in 1986. It contains general guidance from the principal wildlife
management agencies of the two countries for sustaining abundant waterfowl populations by
conserving landscapes through self-directed partnerships (joint ventures) that are guided by
sound science. The CVJV is the joint venture established for overseeing NAWMP implementation
in the Central Valley. The CVJV is made up of 21 conservation organizations, state and federal
government agencies, and one corporation that have formed a partnership to improve the
habitat conditions for breeding and nonbreeding waterfowl, breeding and nonbreeding
shorebirds, waterbirds, and riparian-dependent songbirds in the Central Valley. The CVJV's
2006 Implementation Plan (Central Valley Joint Venture 2006) establishes conservation
objectives and priorities for these bird groups within the basins of the Central Valley. The BDCP
Plan Area includes all or portions of three Implementation Plan basins— the Delta, Yolo and
Suisun basins. The 2006 Implementation Plan contains basin-specific objectives for wetland
restoration, protection of existing wetland habitats, wetland enhancement, adequate power and
water supplies for wetland management, agricultural land enhancement, farmland easements
that maintain waterfowl food resources on agricultural land, and farmland easements that
buffer existing wetlands from urban and residential growth.

Implementation of the Alternative 1B conservation measures would result in significant
reductions in cultivated land and managed wetland acreage in the Delta, Yolo and Suisun basins;
however, significant increases in tidal and nontidal wetlands in these basins would be another
result. Because of the large conversion of managed wetland in the Suisun basin, the BDCP has
included a large managed wetland conservation and enhancement goal for this area. For the
Suisun basin conversions to be compatible with the 2006 Implementation Plan goals, this
EIR/EIS has added mitigation that would require food production studies and adaptive
management to ensure that the Suisun basin would continue to provide the waterfowl and
shorebird habitat envisioned in the Implementation Plan.

- Stone Lakes National Wildlife Refuge Comprehensive Conservation Plan, Cosumnes River Preserve
  Management Plan, Brannan Island and Franks Tract State Recreation Areas General Plan, Yolo
  Bypass Wildlife Area Land Management Plan, Grizzly Island Wildlife Area Management Plan, and
  the Lower Sherman Island Wildlife Area Land Management Plan are primarily designed to
  preserve and enhance the natural resource and recreation qualities of these areas.

Implementing Alternative 1B, especially construction of CM1 and CM2 facilities, and land
modification associated with CM4 restoration activities, could create temporary disruptions to
the terrestrial biological resource management activities in these management areas. The
ultimate goals of aquatic and terrestrial habitat enhancement and restoration contained in the
BDCP would be compatible with the long-term management goals of these areas. Proposed
restoration areas in the Yolo Bypass, on Sherman Island, and in Suisun Marsh would be designed
to be compatible with and to complement the current management direction for these areas and
would be required to adapt restoration proposals to meet current policy established for
managing these areas.

- Suisun Marsh Preservation Agreement and Suisun Marsh Plan are the most recent efforts by the
  state and federal agencies responsible for Suisun Marsh (the Marsh) to maintain its long-term
  viability as managed wetlands and wildlife habitat, consistent with the Suisun Marsh
  Preservation Act. The Suisun Marsh Preservation Agreement (SMPA) was signed in 1987 and
  modified in 2005 by DWR, CDFW, Reclamation and the Suisun Resource Conservation District to
  establish the mitigation approach in the Marsh for effects of operating the SWP and CVP. The
  primary concerns were the effects of CVP and SWP Delta diversions on salinity in the Marsh. The
SMPA focused on ways to ensure adequate water quality and quantity for the managed wetlands and wildlife habitats in the Marsh to assure equal waterfowl values in the Marsh. The Suisun Marsh Plan (SMP), for which a Final EIS/EIR was released in 2010 by these agencies, provides for restoration of tidal marsh habitat and enhancement of managed wetland in the Marsh, maintenance of waterfowl hunting and recreational opportunities in the Marsh, maintenance and improvement of the Marsh levee system, and protection and enhancement of water quality for beneficial uses of the Marsh. An integral component of the SMP is balancing continued managed wetland operation with new tidal wetland restoration to provide improved and greater habitat for fish and wildlife species. The SMP is a programmatic, long-term plan and does not include specific projects, project proponents, or funding mechanisms. However, the SMP relies on tidal restoration to allow for managed wetland operations to continue. The BDCP would provide a funding mechanism and increased management potential relative to existing and restored habitats, assisting the SMP in meeting its broader ecological goals, consistent with long-term operation of the SWP and CVP water conveyance facilities. The conservation actions contained in the BDCP, which are designed to ensure the long-term protection and recovery of special-status fish and wildlife species dependent on the Marsh, would be compatible with the water quality and habitat restoration goals of the SMPA and SMP.

- **California Aquatic Invasive Species Management Plan** does not address terrestrial invasive species. Implementation of the Plan’s long-term control and management objectives affect terrestrial species that utilize study area aquatic habitats. These effects are positive in that Plan objectives are to control and remove invasive aquatic species that are detrimental to native aquatic and terrestrial species. Implementation of BDCP’s conservation actions would be undertaken with the goal of avoiding any further spread of aquatic invasive species. Alternative 1B would, therefore, be compatible with the objectives of the California Aquatic Invasive Species Management Plan.

- **Habitat Conservation Plans and Natural Community Conservation Plans** are the subject of a detailed analysis at the end of this chapter. The analysis considers the compatibility of the BDCP with all HCPs and NCCPs that share planning area with the BDCP Plan Area.

**Executive Orders**

- **Executive Order 11990: Protection of Wetlands** requires all federal agencies to consider wetland protection in their policies and actions. The BDCP proposes to protect, enhance and expand the wetlands of the Plan Area, and, therefore, would be compatible with Executive Order 11990.

- **Executive Order 13112: Invasive Species** directs federal agencies to prevent and control the introduction and spread of invasive species in a cost-effective and environmentally sound manner. Alternative 1B construction and restoration actions have the potential to both introduce and spread invasive species in the study area. Implementation of mitigation measures described in this chapter would be capable of making Alternative 1B implementation compatible with Executive Order 13112.

- **Executive Order 113443: Facilitation of Hunting Heritage and Wildlife Conservation** directs federal agencies whose activities affect public land management, outdoor recreation, and wildlife management to facilitate the expansion and enhancement of hunting opportunities, and the management of game species and their habitat. Alternative 1B conservation measures that involve conversion of cultivated land and managed wetland to tidal and nontidal wetlands and other natural communities would conflict with the hunting expansion and enhancement aspects...
of this executive order. Refer to Chapter 15, *Recreation*, for a detailed analysis of the effects of alternatives on hunting opportunities. The habitat protection and expansion conservation measures of Alternative 1B would be compatible with the executive order’s goal of facilitating the management of habitats for some game species.

**CEQA Conclusion:** The potential plan and policy incompatibilities of implementing Alternative 1B identified in the analysis above indicate the potential for a physical consequence to the environment. The primary physical consequence of concern is the conversion of large acreages of cultivated land and managed wetland to natural wetland and riparian habitat in the study area. The physical effects are discussed in the Shorebirds and Waterfowl analysis above and no additional CEQA conclusion is required related to the compatibility of the alternative with relevant plans and polices. The reader is referred to Section 13.2.3 of Chapter 13, *Land Use*, for a further discussion of the responsibilities of state and federal agencies to comply with local regulations and the relationship between plan and policy consistency and physical consequences to the environment.
