

5.3 Environmental Consequences

5.3.1 Methods for Analysis

The water supply analysis addresses changes to water supply to SWP and CVP water users in the Delta region, upstream of the Delta Region, and Export Service Areas due to implementation of BDCP conveyance facilities (CM1) and other conservation measures, specifically tidal marsh habitat restoration (CM4). Consistent with previous modeling analyses conducted by DWR and Reclamation, including the 2008 Biological Assessment on the Continued Long-Term Operations of the Central Valley Project and State Water Project, the modeling analyses presented in this section assumed that the SWP and CVP were solely responsible for providing any needed water for BDCP implementation. The alternatives would not modify water deliveries to non-SWP and non-CVP water rights holders, including in-Delta water rights holders modify the operations of the SWP and CVP facilities but would not modify the operations of water resources facilities owned and/or operated by other water rights holders. Therefore, the water supply analysis addresses impacts to DWR, Reclamation, and SWP water users and CVP water service contractors, as opposed to other water rights holders, as the BDCP does not include any regulatory actions that would affect water availability to any such water rights holders. Consistent with previous modeling analyses conducted by DWR and Reclamation, including the 2008 Biological Assessment on the Continued Long-Term Operations of the Central Valley Project and State Water Project, the modeling analyses presented in this section assumed that the SWP and CVP were solely responsible for providing any needed water for BDCP implementation. However, water quality of the available water, particularly for in-Delta water rights holders, could vary with different alternatives; and therefore, affect beneficial use of the water rights, as described in Chapter 8, Water Quality.

The water supply analysis was conducted using the CALSIM II model. A brief overview of the modeling tools and outputs is provided in Section 4.3, Overview of Tools, Analytical Methods, and Applications, and a full description of the tools is included in Appendix 5A, BDCP EIR/S Modeling.

CALSIM II is a reservoir-river basin planning model developed by DWR and Reclamation to simulate the operation of the SWP and CVP over a range of different hydrologic conditions. CALSIM II allows for specification and achievement of user-specified allocation targets, or goals. CALSIM II is the best available planning model for the SWP and CVP system operations and has been used in previous system-wide evaluations of SWP and CVP operations (U.S. Bureau of Reclamation, 2004, 2008a). Inputs to CALSIM II include water diversion requirements (demands), stream accretions and depletions, reservoir inflows, irrigation efficiencies, and parameters to calculate return flows, non-recoverable losses and groundwater operations. Sacramento Valley and tributary rim basin hydrologies use an adjusted historical sequence of monthly stream flows over an 82-year period (1922 to 2003) to represent a sequence of flows at a future level of development. Adjustments to historic water supplies are imposed based on future land use conditions and historical meteorological and hydrologic conditions. The resulting hydrology represents the water supply available from Central Valley streams to the CVP and SWP at a future level of development. CALSIM

1 II produces outputs for river flows and diversions, reservoir storage, Delta flows and exports, Delta
 2 inflow and outflow, Deliveries to project and non-project users, and controls on project operations.
 3 Water rights deliveries to non-SWP and non-CVP water rights holders are not modified in the
 4 CALSIM II simulations of the Alternatives.

5 The results of Alternatives simulations are compared to CEQA Existing Conditions simulation and to
 6 the NEPA No Action Alternative simulation to assess potential effects on the SWP and CVP water
 7 supply availability.

8 Under extreme hydrologic and operational conditions where there is not enough water supply to
 9 meet all requirements, CALSIM II utilizes a series of operating rules to reach a solution to allow for
 10 the continuation of the simulation. It is recognized that these operating rules are a simplified version
 11 of the very complex decision processes that SWP and CVP operators would use in actual extreme
 12 conditions. Therefore, model results and potential changes under these extreme conditions should
 13 be evaluated on a comparative basis between alternatives and are an approximation of extreme
 14 operational conditions.

15 As an example, CALSIM II model results show simulated occurrences of extremely low storage
 16 conditions at CVP and SWP reservoirs during critical drought periods when storage is at dead pool
 17 levels at or below the elevation of the lowest level outlet. Simulated occurrences of reservoir storage
 18 conditions at dead pool levels may occur coincidentally with simulated impacts that are determined
 19 to be potentially significant. When reservoir storage is at dead pool levels, there may be instances in
 20 which flow conditions fall short of minimum flow criteria, salinity conditions may exceed salinity
 21 standards, diversion conditions fall short of allocated diversion amounts, and operating agreements
 22 are not met.

23 **5.3.1.1 Quantitative Analysis of SWP and CVP Water Supply Impacts**

24 **Delta Outflow**

25 Criteria for Delta outflow into San Francisco Bay included in Water Rights Decision 1641 and USFWS
 26 and NMFS BiOps, and required by specific requirements of each alternative affect water supply
 27 availability for SWP and CVP water users located north and south of the Delta. Water required for
 28 Delta outflow must flow into San Francisco Bay to improve water quality and conditions for aquatic
 29 resources, as described in Chapter 8, *Water Quality*, and Chapter 11, *Fish and Aquatic Resources*.
 30 Because the water must flow into San Francisco Bay to meet the seasonal flow and volume
 31 requirements, water allocated for Delta outflow is not available for SWP and CVP water users in the
 32 Export Service Areas and may result in limited availability for SWP and CVP water users in the Delta
 33 and upstream of the Delta.

34 Delta outflow requirements also are considered in the determination of the ability to divert water at
 35 the SWP and CVP south Delta intakes to minimize reverse flow conditions. Reverse flow conditions
 36 in Old and Middle Rivers occur when exports exceed the amount of inflow from the San Joaquin
 37 River. Limiting reverse flows in Old and Middle Rivers reduces fish exposure and entrainment at the
 38 south Delta intakes.

39 The alternatives include criteria to maintain freshwater in the western Delta in the spring to meet
 40 SWRCB requirements for X2. Some of the alternatives include criteria to maintain Fall X2 at the
 41 compliance points specified in the 2008 FWS BiOp in wet and above normal years. Some alternatives
 42 include possible locations of tidal marsh restoration areas in the Delta which could alter

hydrodynamic conditions in adjacent Delta channels, including changes in tidal exchange of saline water from San Francisco Bay which could increase salinity in the western Delta, as described in Chapter 8, *Water Quality*. This analysis assumes no changes in the maximum allowable salinity standards (and the related extent of freshwater in the western Delta). Therefore, if operations under the alternatives increase salinity in the western Delta, more water would need to be released from the SWP and CVP reservoirs to avoid exceeding Delta maximum allowable salinity standards. These actions would reduce water in storage at the end of September in the CVP and SWP reservoirs, and less water would be available for SWP and CVP water supplies both upstream and downstream of the Delta.

5.3.1.2 Project- and Program-Level Components

For this analysis, changes in SWP and CVP water supply are evaluated at a project level of detail. It should be noted that SWP/CVP water supply operations are affected both by specific operations criteria identified for each alternative, which are addressed on a project level basis in this EIR/EIS, and by assumptions regarding the location and extent of tidal marsh restoration for each alternative, which are identified only at a programmatic level in this document. Therefore, long-term results of SWP/CVP operations may be different than described due to changes in location and extent of tidal marsh restoration. The analysis assumed that evaporation at the tidal marsh restoration sites would be similar to the water demands of the existing irrigated and non-irrigated vegetation, freshwater marsh and wetlands, or other land uses currently located at the future tidal marsh restoration areas.

5.3.3 Effects and Mitigation Approaches

5.3.3.1 No-Action Alternative

Change in SWP and CVP Reservoir Storage

The exceedance plots in Figures 5-6 through 5-16 show No Action Alternative reservoir end-of-month storage values compared to Existing Conditions. Results for changes in SWP and CVP reservoir storage are presented in more detail in Appendix 5A, *BDCP EIR/S Modeling*. The shift in runoff patterns due to climate change would result in less storage in upstream reservoirs in May and September, as shown in Figures 5-6 through 5-16 and Tables 5-4 through 5-6. Storage reductions in May and September are caused by a combination of higher runoff in January and February that cannot be captured due to flood storage limitations, higher releases to meet Fall X2, and lower carryover storage from previous years due to higher releases for Fall X2 in wet and above normal years, and increased system demands by water rights holders, especially in El Dorado, Placer and Sacramento counties.

In comparison to Existing Conditions, there would be a decrease in carryover storage at the end of September for Lake Oroville, Trinity Lake, Shasta Lake, and Folsom Lake in all years. Lake Oroville storage would decrease by 646 TAF (31%) in September average end of month storage. Trinity, Shasta, and Folsom lakes September carryover would decrease by 230 TAF (17%), 481 TAF (18%), and 146 TAF (28%), respectively under No Action Alternative as compared to Existing Conditions. The frequency of Trinity, Shasta, and Folsom Lakes dropping to dead pool storage would increase by about 10% under the No Action Alternative as compared to Existing Conditions. Changes in San Luis Reservoir storage at the end of September would decrease by 190 TAF (28%) as compared to Existing Conditions. These changes in storage would reduce the ability of the CVP and SWP to meet

1 system water demands and environmental water needs. Adaption measures would need to be
 2 implemented on upstream operations to manage coldwater pool storage levels under future sea
 3 level rise and climate change conditions. As described in the methods section, model results when
 4 storages are at or near dead pool may not be representative of actual future conditions because
 5 changes in assumed operations may be implemented to avoid these conditions.

6 **5.3.3.2 Alternative 1A—Dual Conveyance with Pipeline/Tunnel and** 7 **Intakes 1–5 (15,000 cfs; Operational Scenario A)**

8 **Change in SWP and CVP Reservoir Storage**

9 San Luis Reservoir

10 Average annual end of September San Luis Reservoir storage would increase by 133 TAF (27%)
 11 compared to the No Action Alternative and exhibit an increase in all years, as shown in Tables 5-7
 12 through 5-9 and Appendix 5A-C, CALSIM II and DSM2 Modeling Results.

13 Average annual end of September San Luis Reservoir storage would decrease by 57 TAF (8%)
 14 compared to Existing Conditions and exhibit a decrease in about 90% of the years, as shown in
 15 Tables 5-4 through 5-6 and Appendix 5A-C, CALSIM II and DSM2 Modeling Results. This decrease
 16 primarily would occur due to sea level rise, climate change, and increased north of Delta demands.

17 A comparison with storages under the No Action Alternative provides an indication of the potential
 18 change due to Alternative 1A and the results show that average annual end of September San Luis
 19 Reservoir storage would increase under Alternative 1A as compared to the conditions without the
 20 project.

21 **5.3.3.5 Alternative 2A—Dual Conveyance with Pipeline/Tunnel and Five** 22 **Intakes (15,000 cfs; Operational Scenario B)**

23 **Change in SWP and CVP Reservoir Storage**

24 San Luis Reservoir

25 Average annual end of September San Luis Reservoir storage would decrease by 17 TAF (3%)
 26 compared to the No Action Alternative and exhibit a decrease in 90 % of the years, as shown in
 27 Tables 5-7 through 5-9 and Appendix 5A-C, CALSIM II and DSM2 Modeling Results.

28 Average annual end of September San Luis Reservoir storage would decrease by 207 TAF (30%)
 29 compared to Existing Conditions and exhibit a decrease in about 90% of the years, as shown in
 30 Tables 5-4 through 5-6 and Appendix 5A-C, CALSIM II and DSM2 Modeling Results. This decrease
 31 primarily would occur due to Alternative 2A and due to sea level rise, climate change, and increased
 32 north of Delta demands.

33 A comparison with storages under the No Action Alternative provides an indication of the potential
 34 change due to Alternative 2A and the results show that average annual end of September San Luis
 35 Reservoir storage would increase under Alternative 2A as compared to the conditions without the
 36 project.

5.3.3.8 Alternative 3—Dual Conveyance with Pipeline/Tunnel and Intakes 1 and 2 (6,000 cfs; Operational Scenario A)

Change in SWP and CVP Reservoir Storage

San Luis Reservoir

Average annual end of September San Luis Reservoir storage would increase by 131 TAF (26%) compared to the No Action Alternative and exhibit a decrease in 30 % of the years, as shown in Tables 5-7 through 5-9 and Appendix 5A-C, CALSIM II and DSM2 Modeling Results.

Average annual end of September San Luis Reservoir storage would decrease by -59 TAF (9%) compared to Existing Conditions and exhibit a decrease in about 90% of the years, as shown in Tables 5-4 through 5-6 and Appendix 5A-C, CALSIM II and DSM2 Modeling Results. This decrease primarily would occur due to Alternative 3 and due to sea level rise, climate change, and increased north of Delta demands.

A comparison with storages under the No Action Alternative provides an indication of the potential change due to Alternative 3 and the results show that average annual end of September San Luis Reservoir storage would increase under Alternative 3 as compared to the conditions without the project.

5.3.3.9 Alternative 4—Dual Conveyance with Modified Pipeline/Tunnel and Intakes 2, 3, and 5 (9,000 cfs; Operational Scenario H)

Facilities construction under Alternative 4 would ~~be similar to those described for Alternative 2A with only~~ follow the modified pipeline/tunnel alignment with three intakes, a series of tunnels, an intermediate forebay, and two pumping plants located adjacent to an expanded and divided Clifton Court Forebay. Alternative 4 water conveyance operations would follow the similar operational criteria as Alternative 2A with the exception of evaluating a range of possible operations for the spring and fall Delta outflow requirements that are considered to be equally likely. This range of operations are encompassed by four separate scenarios as described in detail in Section 3.6.4.2 in Chapter 3, Description of Alternatives, and in Appendix 5A, BDCP EIR/S Modeling. These four scenarios vary depending on assumptions for Delta outflow requirements in spring and fall.

Alternative 4 Operational Scenario H1 (Alternative 4 H1) does not include enhanced spring outflow requirements or Fall X2 requirements,

Alternative 4 Operational Scenario H2 (Alternative 4 H2) includes enhanced spring outflow requirements but not Fall X2 requirements,

Alternative 4 Operational Scenario H3 (Alternative 4 H3) does not include enhanced spring outflow requirements but includes Fall X2 requirements (similar to Alternative 2A), and

Alternative 4 Operational Scenario H4 (Alternative 4 H4) includes both enhanced spring outflow requirements and Fall X2 requirements.

A description of the changes in Delta outflow, reservoir storage, Delta exports, and SWP and CVP deliveries is provided below for each scenario. The results for Alternative 4 scenarios include sea level rise and climate change that would occur at late long-term [LLT] around Year 2060. As described in Section 5.3.1 Methods of Analysis, sea level rise and climate change affect SWP and CVP

1 operations and require additional water to be released from SWP and CVP reservoirs to meet Delta
2 water quality requirements.

3 Model simulation results for Alternative 4 (all scenarios) are summarized in Tables 5-7 through 5-9.

4 **Summary of Water Supply Operations under Alternative 4**

5 **Change in Delta Outflow**

6 Changes in average annual Delta outflow under Alternative 4 (all scenarios) as compared to the No
7 Action Alternative and Existing Conditions are shown in Figures 5-3 through 5-5 and Tables 5-7
8 through 5-9.

9 Late-fall and winter outflows remain similar or show minor reductions in all four Alternative 4
10 scenarios compared to No Action Alternative. In the spring months, outflow would decrease under
11 scenarios H1 and H3 as compared to No Action Alternative, while the enhanced spring outflow
12 requirement under scenarios H2 and H4 would result in increased or similar outflow compared to
13 No Action Alternative. SWP and CVP exports in summer months would increase and result in lower
14 outflow under all four scenarios compared to No Action Alternative. In the fall months, outflow
15 would be decreased under Alternative 4 H1 and H2 compared to No Action Alternative, while it
16 would be increasing or remaining similar under scenarios H3 and H4 because of the Fall X2
17 requirement, in wet and above-normal years. All four scenarios would show increased or similar
18 outflow in September and October months of all year types because of OMR flow requirements and
19 export reductions.

20 Long-term average and wet year peak outflows would increase in winter months with a
21 corresponding decrease in spring months because of the shift in system inflows caused by climate
22 change and increased Delta exports as compared to Existing Conditions. In other year types,
23 scenarios H1 and H3 would result in lower or similar outflow in the spring months, while scenarios
24 H2 and H4 would result in higher or similar outflow, because of the enhanced spring outflow
25 requirements. In summer and fall months, all four scenarios would result in similar or higher
26 outflow because of changes in export patterns and OMR flow requirements and export reductions in
27 fall months, and also because of the Fall X2 requirements in scenarios H3 and H4 in wet and above
28 normal years. The incremental changes in Delta outflow between Alternative 4 (all scenarios) and
29 Existing Conditions would be a function of both the facility and operations assumptions of
30 Alternative 4 scenarios (including north Delta intakes capacity of 9,000 cfs, less negative OMR flow
31 requirements, enhanced spring outflow and/or Fall X2 requirements) and the reduction in water
32 supply availability due to increased north of Delta urban demands, sea level rise and climate change.

33 Based on results from all four possible outcomes of the Alternative 4, Delta outflow under
34 Alternative 4 (all scenarios) would likely decrease or remain similar compared to the conditions
35 without the project.

36 Results for changes in Delta Outflow are presented in more detail in Appendix 5A, BDCP EIR/S
37 Modeling.

38 **Change in SWP and CVP Reservoir Storage**

39 Changes in May and September reservoir storage under Alternative 4 (all scenarios) as compared to
40 the No Action Alternative and Existing Conditions are shown in Figures 5-6 through 5-12 and Tables

1 5-7 through 5-9 for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. SWP and CVP San Luis
2 Reservoir storages are presented in figures 5-13 through 5-16 for completeness. Results for changes
3 in SWP and CVP reservoir storages are presented in more detail in Appendix 5A. BDCP EIR/S
4 Modeling.

5 **Trinity Lake**

6 Under Alternative 4 scenarios, average annual end of September Trinity Lake storage as compared
7 to No Action Alternative would range from a decrease of 24 TAF (2%) in about 70% of the years
8 under H3 scenario to an increase of 23 TAF (2%) in about 75% of the years under H2 scenario, as
9 shown in Figure 5-6.

10 Under Alternative 4 scenarios, average annual end of September Trinity Lake storage as compared
11 to Existing Conditions would range from a decrease of 255 TAF (18%) in almost all of the years
12 under H3 scenario to a decrease of 207 TAF (15%) in almost all of the years under H2 scenario, as
13 shown in Figure 5-6. This decrease primarily would occur due to sea level rise, climate change, and
14 increased north of Delta demands.

15 A comparison with storages under the No Action Alternative provides an indication of the potential
16 change due to Alternative 4 and the results show that average annual end of September Trinity Lake
17 storage could decrease or increase under Alternative 4 as compared to the conditions without the
18 project.

19 **Shasta Lake**

20 Under Alternative 4 scenarios, average annual end of September Shasta Lake storage as compared to
21 No Action Alternative would range from a decrease of 60 TAF (3%) in about 75% of the years under
22 H3 scenario to an increase of 142 TAF (6%) in about 90% of the years under H2 scenario, as shown
23 in Figure 5-8.

24 Under Alternative 4 scenarios, average annual end of September Shasta Lake storage as compared to
25 Existing Conditions would range from a decrease of 541 TAF (20%) about 95% of the years under
26 H3 scenario to a decrease of 339 TAF (12%) in about 95% of the years under H2 scenario, as shown
27 in Figure 5-8. This decrease primarily would occur due to sea level rise, climate change, and
28 increased north of Delta demands.

29 A comparison with storages under the No Action Alternative provides an indication of the potential
30 change due to Alternative 4 and the results show that average annual end of September Shasta Lake
31 storage could decrease or increase under Alternative 4 as compared to the conditions without the
32 project.

33 **Lake Oroville**

34 Under Alternative 4 scenarios, average annual end of September Lake Oroville storage as compared
35 to No Action Alternative would range from an increase of 66 TAF (5%) in about 90% of the years
36 under H3 scenario to an increase of 305 TAF (22%) in almost all of the years under H2 scenario, as
37 shown in Figure 5-10.

38 Under Alternative 4 scenarios, average annual end of September Lake Oroville storage as compared
39 to Existing Conditions would range from a decrease of 580 TAF (28%) in almost all of the years
40 under H3 scenario to a decrease of 341 TAF (17%) in about 95% of the years under H2 scenario, as

1 shown in Figure 5-10. This decrease primarily would occur due to sea level rise, climate change, and
2 increased north of Delta demands.

3 A comparison with storages under the No Action Alternative provides an indication of the potential
4 change due to Alternative 4 and the results show that average annual end of September Lake
5 Oroville storage would increase under Alternative 4 as compared to the conditions without the
6 project.

7 **Folsom Lake**

8 Under Alternative 4 scenarios, average annual end of September Folsom Lake storage as compared
9 to No Action Alternative would range from a decrease of 8 TAF (2%) in about 55% of the years
10 under H3 scenario to an increase of 43 TAF (11%) in about 90% of the years under H2 scenario, as
11 shown in Figure 5-12.

12 Under Alternative 4 scenarios, average annual end of September Folsom Lake storage as compared
13 to Existing Conditions would range from a decrease of 154 TAF (29%) about 95% of the years under
14 H3 scenario to a decrease of 103 TAF (20%) in about 90% of the years under H2 scenario, as shown
15 in Figure 5-12. This decrease primarily would occur due to sea level rise, climate change, and
16 increased north of Delta demands.

17 A comparison with storages under the No Action Alternative provides an indication of the potential
18 change due to Alternative 4 and the results show that average annual end of September Folsom Lake
19 storage could decrease or increase under Alternative 4 as compared to the conditions without the
20 project.

21 **San Luis Reservoir**

22 Under Alternative 4 scenarios, average annual end of September San Luis Reservoir storage as
23 compared to No Action Alternative would range from a decrease of 198 TAF (40%) and a decrease
24 in all of the years under H4 scenario to an increase of 71 TAF (14%) and a decrease in storage in
25 about 60% of the years under H1 scenario, as shown in Tables 5-7 through 5-9 and Appendix 5A-C,
26 CALSIM II and DSM2 Modeling Results.

27 Under Alternative 4 scenarios, average annual end of September San Luis Reservoir storage as
28 compared to Existing Conditions would range from a decrease of 388 TAF (29%) and a decrease in
29 all of the years under H4 scenario to a decrease of 119 TAF (17%) and a decrease in about 90% of
30 the years under H1 scenario, as shown in Tables 5-4 through 5-6 and Appendix 5A-C, CALSIM II and
31 DSM2 Modeling Results. This decrease primarily would occur due to sea level rise, climate change,
32 and increased north of Delta demands.

33 A comparison with storages under the No Action Alternative provides an indication of the potential
34 change due to Alternative 4 and the results show that average annual end of September San Luis
35 Reservoir storage would increase under Alternative 4 as compared to the conditions without the
36 project.

37 **Change in Delta Exports**

38 Changes in average annual Delta exports under Alternative 4 scenarios as compared to the No
39 Action Alternative and Existing Conditions are shown in Figures 5-17 through 5-20 and Tables 5-7
40 through 5-9.

1 The addition of the north Delta intakes and changes to Delta regulatory requirements under
 2 Alternative 4 scenarios change SWP and CVP Delta exports as compared to Delta exports under
 3 Existing Conditions and the No Action Alternative.

4 Delta exports would either remain similar or increase under Alternative 4 scenarios as compared to
 5 exports under No Action Alternative depending on the implementation of Fall X2 and/or enhanced
 6 spring outflow requirement. The increase in exports is mainly because of the additional capability to
 7 divert water at the north Delta intakes during winter and spring months.

8 Total long-term average annual Delta exports under Alternative 4 scenarios would decrease as
 9 compared to exports under Existing Conditions reflecting changes in operations due to less negative
 10 OMR flows, implementation of Fall X2 and/or enhanced spring outflow under Alternative 4
 11 scenarios, and sea level rise and climate change.

12 The incremental change in Delta exports under Alternative 4 scenarios as compared to No Action
 13 Alternative would be caused by the facility and operations assumptions of Alternative 4 scenarios
 14 (such as north Delta intakes capacity of 9,000 cfs, Head of Old River Barrier operations and less
 15 negative OMR flows, enhanced spring outflow and Fall X2) only. Delta exports would either remain
 16 similar or increase under Alternative 4 scenarios as compared to the conditions without the project.

17 **Change in SWP and CVP Deliveries**

18 **Impact WS-1: Changes in SWP/CVP Water Deliveries during Construction**

19 **NEPA Effects:** During construction of water conveyance facilities associated with Alternative 4,
 20 operation of existing SWP and CVP water conveyance would continue. Construction would not affect
 21 the timing or amount of water exported from the Delta through SWP and CVP facilities.

22 **CEQA Conclusion:** Constructing Alternative 4 water conveyance facilities would not impact
 23 operation of existing SWP or CVP facilities.

24 **Impact WS-2: Change in SWP and CVP Deliveries**

25 The addition of the north Delta intakes and changes to Delta regulatory requirements under all four
 26 Alternative 4 scenarios provide operational flexibility compared to deliveries under Existing
 27 Conditions and the No Action Alternative.

28 Results for SWP and CVP deliveries are presented in more detail in Appendix 5A, BDCP EIR/S
 29 Modeling.

30 **Total CVP Deliveries**

31 Under Alternative 4 scenarios, the change in average annual total CVP deliveries as compared to No
 32 Action Alternative, would range from an increase of 83 TAF (2%) under H4 scenario to 251 TAF
 33 (6%) under H1 scenario. Under the four Alternative 4 scenarios, the change in average annual total
 34 south of Delta CVP deliveries as compared to No Action Alternative, would range from an increase of
 35 73 TAF (4%) under H4 scenario to 221 TAF (11%) under H1 scenario.

36 Under Alternative 4 scenarios, the change in average annual total CVP deliveries as compared to
 37 Existing Conditions, would range from a decrease of 90 TAF (2%) under H4 scenario to an increase
 38 of 79 TAF (2%) under H1 scenario. Under Alternative 4 scenarios, the change in average annual total

1 south of Delta CVP deliveries as compared to Existing Conditions, would range from a decrease of 59
2 TAF (3%) under H1 scenario to 207 TAF (9%) under H4 scenario.

3 Deliveries compared to No Action Alternative are an indication of the potential change due to
4 Alternative 4 scenarios in the absence of the effects of increased north of delta demands and sea
5 level rise and climate change and the results show that under Alternative 4 scenarios average annual
6 total CVP deliveries would increase by up to 251 TAF (6%) and average annual total south of Delta
7 CVP deliveries would increase by up to 221 TAF (11%) as compared to No Action Alternative.
8 Therefore, average annual total CVP deliveries and average annual total CVP south of Delta
9 deliveries would increase under Alternative 4 scenarios as compared to the conditions without the
10 project.

11 **CVP North of Delta Agricultural Deliveries**

12 Under Alternative 4 scenarios, the change in average annual CVP north of Delta agricultural
13 deliveries as compared to No Action Alternative, would range from an increase of 1 TAF (1%) under
14 H4 scenario to 19 TAF (12%) under H1 scenario. Compared to No Action Alternative, the scenarios
15 H1 and H2 would exhibit similar or increased CVP north of Delta agricultural deliveries in most
16 years, including about 10% of dry years, while scenarios H3 and H4 would exhibit in similar
17 deliveries in most years, as shown in Figure 5-30.

18 Under Alternative 4 scenarios, the change in average annual CVP north of Delta agricultural
19 deliveries as compared to Existing Conditions, would range from a decrease of 54 TAF (23%) under
20 H1 scenario to 72 TAF (31%) under H4 scenario. Compared to Existing Conditions, all four
21 Alternative 4 scenarios exhibit lower CVP north of Delta agricultural deliveries in about 80% years,
22 as shown in Figure 5-30. However, this decrease primarily would occur due to sea level rise and
23 climate change, and increased north of Delta demands.

24 Deliveries compared to No Action Alternative are an indication of the potential change due to
25 Alternative 4 scenarios in the absence of the effects of increased north of delta demands and sea
26 level rise and climate change and the results show that average annual CVP north of Delta
27 agricultural deliveries as compared to No Action Alternative would increase by up to 19 TAF (12%)
28 under Alternative 4 scenarios. Therefore, average annual CVP north of Delta agricultural deliveries
29 would increase under Alternative 4 scenarios as compared to the conditions without the project.

30 **CVP South of Delta Agricultural Deliveries**

31 Under Alternative 4 scenarios, the change in average annual CVP south of Delta agricultural
32 deliveries as compared to No Action Alternative, would range from an increase of 69 TAF (9%)
33 under H4 scenario to 213 TAF (29%) under H1 scenario. Compared to No Action Alternative, the
34 Scenarios H1 and H2 would exhibit increased CVP south of Delta agricultural deliveries in most
35 years, while scenarios H3 and H4 would exhibit increased deliveries in about 50% years and similar
36 deliveries in remaining years, as shown in Figure 5-31.

37 Under Alternative 4 scenarios, the change in average annual CVP south of Delta agricultural
38 deliveries as compared to Existing Conditions, would range from a decrease of 27 TAF (3%) under
39 H1 scenario to 171 TAF (18%) under H4 scenario. Compared to Existing Conditions, the scenarios
40 H1 and H2 would exhibit increased CVP south of Delta agricultural deliveries in about 50% years,
41 while lower deliveries in the remaining years. The scenarios H3 and H4 exhibit similar deliveries in
42 about 30% years, and lower deliveries in the remaining years, as shown in Figure 5-31. However,

1 this decrease primarily would occur due to sea level rise and climate change, and increased north of
2 Delta demands.

3 Deliveries compared to No Action Alternative are an indication of the potential change due to
4 Alternative 4 scenarios in the absence of the effects of increased north of delta demands and sea
5 level rise and climate change and the results show that average annual CVP south of Delta
6 agricultural deliveries as compared to No Action Alternative would increase by up to 213 TAF (29%)
7 under Alternative 4 scenarios. Therefore, average annual CVP south of Delta agricultural deliveries
8 would increase under Alternative 4 scenarios as compared to the conditions without the project.

9 **CVP Settlement and Exchange Contract Deliveries**

10 There would be negligible change to CVP Settlement Contract deliveries during dry and critical years
11 under all four Alternative 4 scenarios as compared to deliveries under the No Action Alternative,
12 with scenarios H1 and H3 showing no change (or less than 1% change) and with scenarios H2 and
13 H4 showing about 23 TAF (1%) increase.

14 Under Alternative 4 scenarios, the change in CVP Settlement Contract deliveries during dry and
15 critical years as compared to Existing Conditions, would range from a decrease of 29 TAF (2%)
16 under H4 scenario to 59 TAF (3%) under H3 scenario. This is due to Shasta Lake storage declining to
17 dead pool more frequently, as described previously, under increased north-of-Delta demands and
18 climate change and sea level rise conditions. As described in the methods section, model results and
19 potential changes under these extreme reservoir storage conditions may not be representative of
20 actual future conditions because changes in assumed operations may be implemented to avoid these
21 conditions.

22 There would be no changes in deliveries to CVP Exchange Contractors under Alternative 4 scenarios.

23 Deliveries compared to No Action Alternative are an indication of the potential change due to
24 Alternative 4 scenarios in the absence of the effects of increased north of delta demands and sea
25 level rise and climate change and the results show that CVP Settlement Contract and CVP Exchange
26 Contractors deliveries during dry and critical years would remain similar (or less than 1% change)
27 or increase by up to 23 TAF (1%) under Alternative 4 scenarios as compared to the deliveries under
28 the No Action Alternative. Therefore, CVP Settlement Contract and CVP Exchange Contractors
29 deliveries during dry and critical years under Alternative 4 scenarios would be similar to the
30 deliveries under the conditions without the project.

31 **CVP North of Delta Municipal and Industrial Deliveries**

32 Under Alternative 4 scenarios, the change in average CVP north of Delta M&I deliveries as compared
33 to No Action Alternative, would range from an increase of 1 TAF (or less than 1% change) under H3
34 and H4 scenarios to 7 TAF (2%) under H1 scenario. Compared to No Action Alternative, the
35 scenarios H1, H2, H3 and H4 would exhibit similar deliveries in all years, as shown in Figure 5-32.

36 Under Alternative 4 scenarios, the change in average annual CVP north of Delta M&I deliveries as
37 compared to Existing Conditions, would range from an increase of 172 TAF (82%) under H3 and H4
38 scenarios to 178 TAF (85%) under H1 scenario. Compared to Existing Conditions, the 4 scenarios
39 H1, H2, H3 and H4 would exhibit higher deliveries in all years, as shown in Figure 5-32. However,
40 this increase primarily would occur because there would be an increase in north of Delta M&I water
41 rights demands under Alternative 4 scenarios and No Action Alternative as compared to demands
42 under Existing Conditions.

1 Deliveries compared to No Action Alternative are an indication of the potential change due to
 2 Alternative 4 scenarios in the absence of the effects of increased north of delta demands and sea
 3 level rise and climate change and the results show that average annual CVP north of Delta M&I
 4 deliveries would remain similar or increase by up to 7 TAF (2%) under Alternative 4 scenarios as
 5 compared to the deliveries under the No Action Alternative. Therefore, average annual CVP north of
 6 Delta M&I deliveries would increase under Alternative 4 scenarios as compared to the conditions
 7 without the project.

8 **CVP South of Delta Municipal and Industrial Deliveries**

9 Under Alternative 4 scenarios, the change in average CVP south of Delta M&I deliveries as compared
 10 to No Action Alternative, would range from an increase of 4 TAF (4%) under H3 and H4 scenarios to
 11 9 TAF (9%) under H1 and H2 scenarios. Compared to No Action Alternative, the Scenarios H1 and
 12 H2 exhibit increased deliveries in about 60% of the years, while scenarios H3 and H4 would exhibit
 13 increased deliveries in about 20% of the wetter years, and all scenarios exhibit similar deliveries in
 14 the remaining years, as shown in Figure 5-33.

15 Under Alternative 4 scenarios, the change in average annual CVP south of Delta M&I deliveries as
 16 compared to Existing Conditions, would range from a decrease of 4 TAF (3%) under H1 and H2
 17 scenarios to 9 TAF (7%) under H4 scenario. Compared to Existing Conditions, the scenarios H1, H2,
 18 H3 and H4 would exhibit higher or similar deliveries in about 60% of the years and lower deliveries
 19 in the remaining, as shown in Figure 5-33. However, this decrease primarily would occur due to sea
 20 level rise and climate change, and increased north of Delta demands.

21 Deliveries compared to No Action Alternative are an indication of the potential change due to
 22 Alternative 4 scenarios in the absence of the effects of increased north of delta demands and sea
 23 level rise and climate change and the results show that average annual CVP south of Delta M&I
 24 deliveries would remain similar or increase by up to 9 TAF (9%) under Alternative 4 scenarios as
 25 compared to the deliveries under the No Action Alternative. Therefore, average annual CVP south of
 26 Delta M&I deliveries would increase under Alternative 4 scenarios as compared to the conditions
 27 without the project.

28 **Total SWP Deliveries**

29 Under Alternative 4 scenarios, the change in average annual total SWP deliveries as compared to No
 30 Action Alternative, would range from a decrease of 91 TAF (3%) under H4 scenario to an increase of
 31 582 TAF (17%) under H1 scenario. Under Alternative 4 scenarios, the change in average annual
 32 total south of the Delta SWP deliveries, including Table A (including Article 56) plus Article 21
 33 deliveries, as compared to No Action Alternative, would range from a decrease of 94 TAF (4%)
 34 under H4 scenario to an increase of 566 TAF (24%) under H1 scenario. Compared to No Action
 35 Alternative, the scenarios H1 and H3 exhibit increased deliveries in about 70% of the years and
 36 similar deliveries in remaining years, while scenarios H2 and H4 would exhibit increased deliveries
 37 in about 30% of the wetter years. Scenario H2 exhibits similar deliveries and scenario H4 exhibits
 38 lower deliveries in the remaining years, as shown in Figure 5-34.

39 Under Alternative 4 scenarios, the change in average annual total SWP deliveries as compared to
 40 Existing Conditions, would range from a decrease of 485 TAF (13%) under H4 scenario to an
 41 increase of 187 TAF (5%) under H1 scenario. Under Alternative 4 scenarios, the change in average
 42 annual total south of the Delta SWP deliveries, including Table A (including Article 56) plus Article
 43 21 deliveries, as compared to Existing Conditions, would range from a decrease of 464 TAF (17%)

1 under H4 scenario to an increase of 196 TAF (7%) under H1 scenario. Compared to Existing
 2 Conditions, the Scenarios H1 and H3 exhibit increased deliveries in about 60% of the years and
 3 lower deliveries in remaining years, while scenarios H2 and H4 would exhibit increased deliveries in
 4 about 20% of the wetter years and lower deliveries in the remaining years, as shown in Figure 5-34.

5 Deliveries compared to No Action Alternative are an indication of the potential change due to
 6 Alternative 4 scenarios without the effects of sea level rise and climate change and the results show
 7 that under Alternative 4 scenarios average annual total SWP deliveries would decrease by up to 91
 8 TAF (3%) or increase by up to 582 TAF (17%) and average annual total south of Delta SWP
 9 deliveries would decrease by up to 94 TAF (4%) or increase by up to 566 TAF (24%) as compared to
 10 No Action Alternative. Therefore, average annual total SWP deliveries and average annual total SWP
 11 south of Delta deliveries under Alternative 4 scenarios would show a small decrease or an increase
 12 as compared to the conditions without the project.

13 **SWP Table A Deliveries**

14 Under Alternative 4 scenarios, the change in average annual total SWP Table A deliveries with
 15 Article 56 (without Article 21) as compared to No Action Alternative, would range from a decrease
 16 of 175 TAF (7%) under H4 scenario to an increase of 489 TAF (21%) under H1 scenario. Under
 17 Alternative 4 scenarios, the change in average annual total south of the Delta SWP Table A deliveries
 18 with Article 56 (without Article 21), as compared to No Action Alternative, would range from a
 19 decrease of 171 TAF (7%) under H4 scenario to an increase of 475 TAF (21%) under H1 scenario.
 20 Compared to No Action Alternative, the Scenarios H1 and H3 exhibit increased deliveries in about
 21 70% of the years and similar deliveries in remaining years, while scenarios H2 and H4 would exhibit
 22 increased deliveries in about 20% of the wetter years. In the remaining years, scenario H3 exhibits
 23 similar deliveries and scenario H4 exhibits lower deliveries, as shown in Figure 5-35.

24 Under Alternative 4 scenarios, the change in average annual total SWP Table A deliveries with
 25 Article 56 (without Article 21) as compared to Existing Conditions, would range from a decrease of
 26 438 TAF (17%) under H4 scenario to an increase of 226 TAF (9%) under H1 scenario. Under
 27 Alternative 4 scenarios, the change in average annual total south of the Delta SWP Table A deliveries
 28 with Article 56 (without Article 21), as compared to Existing Conditions, would range from a
 29 decrease of 446 TAF (17%) under H4 scenario to an increase of 201 TAF (8%) under H1 scenario.
 30 Compared to Existing Conditions, the Scenarios H1 and H3 exhibit increased deliveries in about 60%
 31 of the years and lower deliveries in remaining years, while scenarios H2 and H4 would exhibit
 32 increased deliveries in about 20% of the wetter years and lower deliveries in the remaining years, as
 33 shown in Figure 5-35.

34 Deliveries under the No Action Alternative are an indication of the potential change due to
 35 Alternative 4 scenarios in the absence of the effects of increased north of delta demands and sea
 36 level rise and climate change and the results show that under Alternative 4 scenarios average annual
 37 total SWP Table A deliveries with Article 56 (without Article 21) would decrease by up to 175 TAF
 38 (7%) or increase by up to 489 TAF (21%) and average annual total south of Delta SWP Table A
 39 deliveries with Article 56 (without Article 21) would decrease by up to 171 TAF (7%) or increase by
 40 up to 475 TAF (21%) as compared to No Action Alternative. Therefore, average annual total SWP
 41 Table A deliveries with Article 56 (without Article 21) and average annual total SWP south of Delta
 42 Table A deliveries with Article 56 (without Article 21) would show a small decrease or an increase
 43 under Alternative 4 scenarios as compared to the conditions without the project.

1 SWP Article 21 Deliveries

2 Under Alternative 4 scenarios, the change in average annual total SWP Article 21 deliveries as
 3 compared to No Action Alternative, would range from an increase of 60 TAF (126%) under H3
 4 scenario to 91 TAF (192%) under H1 and H2 scenarios. Compared to No Action Alternative, the
 5 Scenarios H1, H2 H3 and H4 exhibit increased deliveries in about same number of years as in No
 6 Action Alternative, although increased SWP Article 21 deliveries are observed in about all 40% of
 7 the years where Article 21 deliveries are made. (Figure 5-36).

8 Under Alternative 4 scenarios, the change in average annual total SWP Article 21 deliveries as
 9 compared to Existing Conditions, would range from a decrease of 20 TAF (13%) under H1 and H2
 10 scenarios to 51 TAF (32%) under H3 scenario. Compared to Existing Conditions, the Scenarios H1,
 11 H2, H3, and H4 exhibit similar or decreased deliveries in about same number of years as in Existing
 12 Conditions, as shown in Figure 5-36.

13 Deliveries compared to No Action Alternative are an indication of the potential change due to
 14 Alternative 4 scenarios in the absence of the effects of increased north of delta demands and sea
 15 level rise and climate change and the results show that average annual Article 21 deliveries would
 16 increase by up to 91 TAF (192%) under Alternative 4 scenarios as compared to the deliveries under
 17 the No Action Alternative. Therefore, average annual Article 21 deliveries would increase under
 18 Alternative 4 scenarios as compared to the conditions without the project.

19 SWP Feather River Service Area

20 Under Alternative 4 scenarios, the change in average annual total SWP Feather River Service Area
 21 deliveries during dry and critical years as compared to No Action Alternative, would range from an
 22 increase of 5 TAF (1%) under H1 and H3 scenarios to 17 TAF (2%) under H4 scenario.

23 Under Alternative 4 scenarios, the change in average annual total SWP Feather River Service Area
 24 deliveries during dry and critical years as compared to Existing Conditions, would range from a
 25 decrease of 38 TAF (4%) under H4 scenario to 50 TAF (6%) under H1 and H3 scenarios. The
 26 primary cause of this reduction would be change in SWP operations due to sea level rise and climate
 27 change.

28 Deliveries compared to No Action Alternative are an indication of the potential change due to
 29 Alternative 4 scenarios in the absence of the effects of increased north of delta demands and sea
 30 level rise and climate change and the results show that average annual SWP Feather River Service
 31 Area deliveries would increase by up to 17 TAF (2%) under Alternative 4 scenarios as compared to
 32 the deliveries under No Action Alternative. Therefore, average annual SWP Feather River Service
 33 Area deliveries would increase under Alternative 4 scenarios as compared to the conditions without
 34 the project.

35 **NEPA Effects:** SWP and CVP deliveries under Alternative 4 as compared to deliveries under No
 36 Action Alternative would increase. Indirect effects of changes in water deliveries in addition to
 37 potential effects on urban areas caused by changes in SWP and CVP water supply deliveries, are
 38 addressed in Chapter 30, Growth Inducement and Other Indirect Effects, and other chapters
 39 addressing specific resources.

40 **CEQA Conclusion:** SWP and CVP deliveries under Alternative 4 would decline as compared to
 41 deliveries under Existing Conditions. The primary cause of the reduction is increased north of Delta
 42 water demands that would occur under No Action Alternative and Alternative 4 and changes in SWP

1 and CVP operations due to sea level rise and climate change. As shown above in the NEPA analysis,
2 SWP and CVP deliveries would generally increase under Alternative 4 as compared to deliveries
3 under conditions in 2060 without Alternative 4 if sea level rise and climate change conditions are
4 considered the same under both scenarios. SWP and CVP deliveries under Alternative 4 would
5 generally increase as compared to deliveries under Existing Conditions without the effects of
6 increased north of Delta water demands, sea level rise, and climate change. Some reductions in the
7 SWP south of Delta deliveries could occur under the Alternative 4 scenarios with enhanced spring
8 outflow. Indirect effects of changes in water deliveries in addition to potential effects on urban areas
9 caused by changes in SWP and CVP water supply deliveries are addressed in Chapter 30, Growth
10 Inducement and Other Indirect Effects, and other chapters addressing specific resources.

11 **Impact WS-3: Effects of Water Transfers on Water Supply**

12 Alternative 4 increases project water supply allocations as compared to the No Action Alternative,
13 and consequently will decrease cross-Delta water transfer demand compared to that alternative.
14 The four scenarios under Alternative 4 would change the combined SWP Table A and CVP south-of-
15 Delta agricultural water supply allocations as compared to existing conditions, and the frequency of
16 years in which cross-Delta transfers are assumed to be triggered would change as well, assuming an
17 estimated cross-Delta transfer supply of 600,000 acre-feet in any one year.

18 For Scenario H1 compared to existing conditions, the frequency of years in which cross-Delta
19 transfers would decrease from 52% to 49%, and the average annual volume of those transfers
20 would increase from 146,000 acre-feet to 187,000 acre-feet. For Scenario H1 compared to the No
21 Action Alternative, the frequency of years in which cross-Delta transfers would decrease from 68%
22 to 49%, the average annual volume of those transfers would decrease from 280,000 acre-feet to
23 187,000 acre-feet.

24 For Scenario H2 compared to existing conditions, the frequency of years in which cross-Delta
25 transfers would increase from 52% to 55%, and the average annual volume of those transfers would
26 increase from 146,000 acre-feet to 212,000 acre-feet. For Scenario H2 compared to the No Action
27 Alternative, the frequency of years in which cross-Delta transfers would decrease from 68% to 55%,
28 the average annual volume of those transfers would decrease from 280,000 acre-feet to 212,000
29 acre-feet.

30 For Scenario H3 compared to existing conditions, the frequency of years in which cross-Delta
31 transfers would increase from 52% to 57%, and the average annual volume of those transfers would
32 increase from 146,000 acre-feet to 227,000 acre-feet. For Scenario H3 compared to the No Action
33 Alternative, the frequency of years in which cross-Delta transfers would decrease from 68% to 57%,
34 the average annual volume of those transfers would decrease from 280,000 acre-feet to 227,000
35 acre-feet.

36 For Scenario H4 compared to existing conditions, the frequency of years in which cross-Delta
37 transfers would increase from 52% to 66%, and the average annual volume of those transfers would
38 increase from 146,000 acre-feet to 279,000 acre-feet. For Scenario H4 compared to the No Action
39 Alternative, the frequency of years in which cross-Delta transfers would decrease from 68% to 66%,
40 the average annual volume of those transfers would decrease from 280,000 acre-feet to 279,000
41 acre-feet.

42 Alternative 4 provides a separate cross-Delta facility with additional capacity to move transfer water
43 from areas upstream of the Delta to export service areas and provides a longer transfer window

1 than allowed under current regulatory constraints. In addition, the facility provides conveyance that
 2 would not be restricted by Delta reverse flow concerns or south Delta water level concerns. As a
 3 result of avoiding those restrictions, transfer water could be moved at any time of the year that
 4 capacity exists in the combined cross-Delta channels, the new cross-Delta facility, and the export
 5 pumps, depending on operational and regulatory constraints, including BDCP permit terms as
 6 discussed in Alternative 1A.

7 NEPA Effects: Alternative 4 would decrease water transfer demand compared to existing conditions.
 8 Alternative 4 would decrease conveyance capacity, enabling additional cross-Delta water transfers
 9 that could lead to increases in Delta exports when compared to No Action Alternative. Prior to
 10 approval, each transfer must go through NEPA review and be evaluated by the export facility agency,
 11 and may also be subject to CEQA review and/or SWRCB process. Indirect effects of changes in Delta
 12 exports or water deliveries are addressed in Chapter 30, Growth Inducement, and other chapters
 13 addressing specific resources.

14 **CEQA Conclusion:** Alternative 4 would increase water transfer demand compared to existing
 15 conditions. Alternative 4 would increase conveyance capacity, enabling additional cross-Delta water
 16 transfers that could lead to increases in Delta exports when compared to existing conditions. Prior
 17 to approval, each transfer must go through the CEQA and/or SWRCB process and be evaluated by
 18 the export facility agency, and may also be subject to NEPA review. Indirect effects of changes in
 19 Delta exports or water deliveries are addressed in Chapter 30, Growth Inducement, and other
 20 chapters addressing specific resources.

21 **5.3.3.10 Alternative 5—Dual Conveyance with Pipeline/Tunnel and** 22 **Intake 1 (3,000 cfs; Operational Scenario C)**

23 **Change in SWP and CVP Reservoir Storage**

24 San Luis Reservoir

25 Average annual end of September San Luis Reservoir storage would decrease by 23 TAF (5%)
 26 compared to the No Action Alternative and exhibit a decrease in 90 % of the years, as shown in
 27 Tables 5-7 through 5-9 and Appendix 5A-C, CALSIM II and DSM2 Modeling Results.

28 Average annual end of September San Luis Reservoir storage would decrease by 213 TAF (31%)
 29 compared to Existing Conditions and exhibit a decrease in all of the years, as shown in Tables 5-4
 30 through 5-6 and Appendix 5A-C, CALSIM II and DSM2 Modeling Results. This decrease primarily
 31 would occur due to Alternative 5 and due to sea level rise, climate change, and increased north of
 32 Delta demands.

33 A comparison with storages under the No Action Alternative provides an indication of the potential
 34 change due to Alternative 5 and the results show that average annual end of September San Luis
 35 Reservoir storage would decrease under Alternative 5 as compared to the conditions without the
 36 project.

1 **5.3.3.11 Alternative 6A—Isolated Conveyance with Pipeline/Tunnel and**
 2 **Intakes 1–5 (15,000 cfs; Operational Scenario D)**

3 **Change in SWP and CVP Reservoir Storage**

4 **San Luis Reservoir**

5 Average annual end of September San Luis Reservoir storage would decrease by 193 TAF (39%)
 6 compared to the No Action Alternative and exhibit a decrease in all of the years, as shown in Tables
 7 5-7 through 5-9 and Appendix 5A-C, CALSIM II and DSM2 Modeling Results.

8 Average annual end of September San Luis Reservoir storage would decrease by 383 TAF (56%)
 9 compared to Existing Conditions and exhibit a decrease in all of the years, as shown in Tables 5-4
 10 through 5-6 and Appendix 5A-C, CALSIM II and DSM2 Modeling Results. This decrease primarily
 11 would occur due to Alternative 6A and due to sea level rise, climate change, and increased north of
 12 Delta demands.

13 A comparison with storages under the No Action Alternative provides an indication of the potential
 14 change due to Alternative 6A and the results show that average annual end of September San Luis
 15 Reservoir storage would ~~increase~~ decrease under Alternative 6A as compared to the conditions without the
 16 project.

17 **5.3.3.14 Alternative 7—Dual Conveyance with Pipeline/Tunnel, Intakes 2,**
 18 **3, and 5, and Enhanced Aquatic Conservation (9,000 cfs;**
 19 **Operational Scenario E)**

20 **Change in SWP and CVP Reservoir Storage**

21 **San Luis Reservoir**

22 Average annual end of September San Luis Reservoir storage would decrease by 179 TAF (36%)
 23 compared to the No Action Alternative and exhibit a decrease in all of the years, as shown in Tables
 24 5-7 through 5-9 and Appendix 5A-C, CALSIM II and DSM2 Modeling Results.

25 Average annual end of September San Luis Reservoir storage would decrease by 369 TAF (54%)
 26 compared to Existing Conditions and exhibit a decrease in all of the years, as shown in Tables 5-4
 27 through 5-6 and Appendix 5A-C, CALSIM II and DSM2 Modeling Results. This decrease primarily
 28 would occur due to Alternative 7 and due to sea level rise, climate change, and increased north of
 29 Delta demands.

30 A comparison with storages under the No Action Alternative provides an indication of the potential
 31 change due to Alternative 7 and the results show that average annual end of September San Luis
 32 Reservoir storage would ~~increase~~ decrease under Alternative 7 as compared to the conditions without the
 33 project.

1 **5.3.3.15 Alternative 8—Dual Conveyance with Pipeline/Tunnel, Intakes 2,**
 2 **3, and 5, and Increased Delta Outflow (9,000 cfs; Operational**
 3 **Scenario F)**

4 **Change in SWP and CVP Reservoir Storage**

5 **San Luis Reservoir**

6 Average annual end of September San Luis Reservoir storage would decrease by 329 TAF (66%)
 7 compared to the No Action Alternative and exhibit a decrease in all of the years, as shown in Tables
 8 5-7 through 5-9 and Appendix 5A-C, CALSIM II and DSM2 Modeling Results.

9 Average annual end of September San Luis Reservoir storage would decrease by 519 TAF (76%)
 10 compared to Existing Conditions and exhibit a decrease in all of the years, as shown in Tables 5-4
 11 through 5-6 and Appendix 5A-C, CALSIM II and DSM2 Modeling Results. This decrease primarily
 12 would occur due to Alternative 8 and due to sea level rise, climate change, and increased north of
 13 Delta demands.

14 A comparison with storages under the No Action Alternative provides an indication of the potential
 15 change due to Alternative 8 and the results show that average annual end of September San Luis
 16 Reservoir storage would decrease under Alternative 8 as compared to the conditions without the
 17 project.

18 **5.3.3.16 Alternative 9—Through Delta/Separate Corridors (15,000 cfs;**
 19 **Operational Scenario G)**

20 **Change in SWP and CVP Reservoir Storage**

21 **San Luis Reservoir**

22 Average annual end of September San Luis Reservoir storage would decrease by 51 TAF (10%)
 23 compared to the No Action Alternative and exhibit a decrease in 90 % of the years, as shown in
 24 Tables 5-7 through 5-9 and Appendix 5A-C, CALSIM II and DSM2 Modeling Results.

25 Average annual end of September San Luis Reservoir storage would decrease by 241 TAF (35%)
 26 compared to Existing Conditions and exhibit a decrease in all of the years, as shown in Tables 5-4
 27 through 5-6 and Appendix 5A-C, CALSIM II and DSM2 Modeling Results. This decrease primarily
 28 would occur due to sea level rise, climate change, and increased north of Delta demands.

29 A comparison with storages under the No Action Alternative provides an indication of the potential
 30 change due to Alternative 9 and the results show that average annual end of September San Luis
 31 Reservoir storage would decrease under Alternative 9 as compared to the conditions without the
 32 project.
 33
